Prevention of Shoulder Dislocations During Convulsive Therapy.—Rechtman and Winkelman devised a support for preventing dislocations of the shoulder in schizophrenic patients during convulsive attacks induced by metrazol. The support prevents abduction of the shoulder joint during the initial

phase of the convulsive attack when the arms are forcibly and violently abducted. With the use of their belt support they have had no further shoulder dislocations. The support consists of a pelvic band not unlike a polo belt. A pair of wrist cuffs are fastened through loops to the lower strap on the pelvic band. A pair of forearm cuffs are fastened through loops to the canvas belt so as to allow sufficient room for making the injection into the vein at the elbow. The pelvic belt is attached firmly, but not tightly, to the patient before the injection is given. The wrist and forearm cuffs are closed with the arm into which the injection will be made held in supination.

Propadrine for Allergic Manifestations.—Murphy used propadrine (phenyl-propanol-amino-hydrochloride), one of many synthetic compounds offered as a bronchodilator and local vasoconstrictor, in the treatment of approximately 200 patients with bronchial and nasal allergies. Dose for dose the clinical relief closely paralleled that of ephedrine, with untoward side effects definitely less although not entirely absent. The tremor, tachycardia, insomnia, occasional nausea, retention of urine in the elderly man and sense of muscular weakness so frequently observed with the use of ephedrine, necessitating combining it with a sedative, were not evident when propadrine was used. The three-eighths grain (0.024 Gm.) recommended by the distributors of the drug was less satisfactory as a starting dose than three-fourths grain (0.05 Gm.), except in children. Propadrine has not been found efficacious in the severer episodes of asthma and hay fever, but under these conditions, as with ephedrine, it was more apt to aid hay fever than asthma.

*Prognostic Value of Cholesterol Partition Study. D. A. Meiselas, Brooklyn.—p. 441.

Treatment of Duodenal Ulcer with Histaminase.—Nakada treated seven patients who had duodenal ulcer with histamine hydrochloride detoxifying substance or histaminase. The subjective symptoms (pain, nausea, belching and nervousness) were promptly relieved in all the patients. Temporary recurrences of symptoms were due to intercurrent infections in two patients

and to faulty cooperation in two others. However, each improved again on recovery from the intercurrent infection or on resumption of cooperation. Histaminase promises to be of considerable value in the treatment of duodenal ulcer, provided future studies give like results. The method of procedure was to keep the patient on a diet free of condiments, alcohol, fatty or fried foods, dressings, thickened gravies, pastries and excessively sweet foods. Coffee was allowed once a day. Nicotine was reduced as much as possible. One ampule of histaminase (containing 1 detoxicating unit of histamine hydrochloride) was given intramuscularly three times a week and one tablet (containing 5 units) was prescribed three times a day one hour before meals. The patients were usually given one or the other first for a week or two. An additional tablet was taken if the patient awoke at night. The rapidity with which the dosage can be reduced and finally eliminated depends on the progress of the patient. After treatment is discontinued, the patient should be examined clinically and roentgenologically about every six months until all objective evidence has disappeared.

Cholesterol Curve in Liver and Gallbladder Diseases.—Meiselas emphasizes the diagnostic and prognostic value of the cholesterol ester curve in cases of jaundice in determining the severity and likelihood of recovery in liver and gallbladder disease. He does not wish to imply that other laboratory tests of hepatic function should be dispensed with but claims that the cholesterol test should be used as an adjunct to them.

Testosterone Propionate and Impotence.—None of eight patients with psychic impotence that Rennie and his co-workers treated with injections of testosterone propionate reported improvement. No change in symptoms was observed in a male homosexual patient similarly treated. If the factor of suggestion is ruled out it seems unlikely to the authors, in spite of other reports, that in states of psychic impotence specific testis hormones in doses adequate for excellent responses in hypogonadal patients offer any therapeutic help.

Effect of Gold Therapy on Sedimentation Rate in Arthritis.—Goldie discusses the effect of gold salt therapy on the blood sedimentation rate in 400 cases of rheumatoid arthritis. The patients have been under observation for from six months to four years. The blood sedimentation rate has been determined before and at the end of each course of treatment. On humanitarian grounds a control series has been observed. Gold treatment produced a marked fall in the blood sedimentation rate, and the higher the initial figure the greater the fall. While the initial figure is valueless from a prognostic point of view, the change in the blood sedimentation rate is of definite value. The greater the fall and the lower the final figure, the better, on an average, was the clinical result. The mean fall in the rate was entirely determined by the fall taking place at the end of the first course of treatment. Reduction of dosage should take place after the first course. The blood sedimentation rate was of little value in anticipating either relapse or severe toxic reactions. The most severe upsets occurred in the presence of a normal rate. The utility of the test is thus considerably lessened from a practical point of view.

*Renal Lesions in Children with Erythema Nodosum. A. Wallgren.—p. 271.

Renal Lesions in Erythema Nodosum.—Wallgren encountered three children with erythema nodosum in whom acute hemorrhagic nephritis appeared simultaneously with the cutaneous eruption. All three children were tuberculin sensitive, and it is thought that the tuberculous infection directly or indirectly played a part in the occurrence of the erythema nodosum. In one of the cases pronounced primary pulmonary tuberculosis was present at the same time. Assuming that subclinical renal changes in erythema nodosum might be much more common than can be gathered from the limited number of clinically obvious cases, the author examined by the Addis method the urine of eighty-eight children with erythema nodosum. A pathologic erythrocyturia was demonstrable in about every third or fourth child. After the disappearance of the erythema and the accompanying fever the urine became normal again. The renal lesions occurred in children who did not display the least evidence of a complicating throat infection and just as often in those with negative as in those with positive tuberculin reactions. Therefore there is no reason for assuming either that a tuberculous or that a streptococcal infection is a requisite condition for the occurrence of pathologic erythrocyturia. Tests showed that in children with erythema nodosum there is often capillary fragility during the erythema nodosum fever. This capillary fragility occurred with about the same frequency in children with pathologic erythrocyturia as in those in whom this sign was not present. Capillary fragility is thought to be due to a toxic

action on the vascular endothelium. The renal lesions are probably to be regarded as an expression of the same remote toxic or allergic action of the infectious agent as that which produced the eruption of erythema nodosum and the capillary fragility of the skin.

Diphenyl Hydantoinate for Mental Disorders.—Davidson and Sutherland have recently use sodium diphenyl hydantoinate (epanutin) in the treatment of twelve epileptic patients with mental symptoms. The drug was administered by gradual replacement of the drug already in use. Most of the patients were more than 40 years of age and had a long history of hospitalization and correspondingly long treatment with drugs. They were almost all admitted for psychotic behavior as well as fits. The most prominent result of the treatment was the appearance of toxic effects; in eight of the twelve patients they occurred within a few weeks. The toxic effects included headache, giddiness, nausea, loss of appetite and ataxia. Rashes developed in three patients. These effects have already been referred to in connection with this preparation, but their frequent and early appearance obviously restrict the use of the drug, for though some are possibly not serious in themselves they antagonized these patients. The three youngest patients showed no toxic effects. Only one patient showed mental improvement, but this lasted for only a few weeks, after which he lapsed into the former state. This patient also showed a temporary improvement on a change from soluble phenobarbital to methyl-ethyl-phenobarbital or vice versa. The effect of the change to sodium diphenyl hydantoinate was rather more marked. His relapse followed the recurrence of fits. It would appear that in his case, as in some of the others, this drug makes a useful addition to those on which patients can be maintained for a few weeks. The absence of sedative effect proved an undesirable feature with several patients, as it released the excessive irritability and, in some cases, impulsive behavior which was relieved by other drugs. Sodium diphenyl hydantoinate had little effect on the character and number of fits in most cases. However, there was a balance in favor of this drug. The authors' experience suggests that the drug is of use for the younger and better preserved patients, but owing to its toxic effects it is advisable not to use it for more than a few weeks at a time.

Infantile Mastoiditis.—In 146 recent consecutive necropsies Leathart found that mastoiditis undiagnosed in life had been present on one or both sides in twenty-nine cases. The frequency with which mastoiditis complicates other diseases has not been sufficiently realized. The eustachian tube is more horizontal in children than in adults, and normally it opens with each act of deglutition. Because of this horizontal position any material in the postnasal space finds its way through the eustachian tube into the tympanum and then to the mastoid antrum more easily than in adults, especially if the child is lying on his back while feeding. This anatomic difference shows how easily infected mucus can enter the tympanum from the postnasal space in air-borne diseases and how vomited material may do so in food-borne diseases. As a rule there is no discharge from the ear, and swelling behind it is never present at a stage when treatment is imperative. Moreover, often the child is too young to complain. Nevertheless mastoiditis can be recognized in children at an early stage by the presence of local physical signs other than those usually associated with mastoiditis. If

a child suffering from an air-borne or food-borne infection or a wasted bottle-fed infant does not improve, mastoiditis is likely to be the cause and should always be suspected. The child with an increase in temperature, crying out as if in pain, putting his hand to his head, pulling at his ear or rolling his head on his pillow should suggest mastoiditis. There is one physical sign which is constant. It consists in the presence of a palpable gland or glands in the posterior triangle of the neck behind the sternomastoid muscle. They are small at first but increase in size with the chronicity of the mastoid infection. Other conditions produce enlargement of these glands, but mastoiditis in its catarrhal or purulent stage is by far the most common. An immediate operation is not necessary in every case, for in some instances mastoiditis in its early stage subsides spontaneously. Immediate operation is necessary only for a child whose general condition is not improving and who is losing weight and becoming dehydrated. Children suffering from air-borne infection, diarrhea and vomiting or wasted bottle-fed infants should never be fed while lying down, nor should they be allowed to lie on their backs for any length of time. Frequent turning of these infants has led to a definite decrease in the frequency of mastoiditis as a complication in these diseases and has proved a potent factor in promoting spontaneous recovery in infants as yet not ill enough to require operation. Mastoidectomy will save the lives of about 70 per cent of the children in whom mastoiditis is complicating an air-borne or food-borne infection.

ridge, Gwendoline Briggs, D. P. Choyce and Janet Hill.—p. 781.

Hernia Through Foramen of Winslow. M. Silverstone.—p. 786.

Defective Hearing and Nutrition in Children.—Kerridge and her associates tested the hearing acuity of sample groups of children in Great Britain who lived under different social conditions. In one series the children were chosen from good environments in private schools, day schools and boarding schools; in another series they were in public elementary schools or in ecclesiastical orphanages. The latter were chosen because they represented institutions which were hard pressed for funds. The children were between 7 and 14. They were tested with a gramophone audiometer. Every child was given a second chance of doing the test before being classed as a failure. Children who failed the second time were tested individually, and in most cases a teacher's report on their mental capabilities was obtained. A medical history was obtained whenever possible. The ears were examined with an auroscope to detect wax; but, since time did not permit of retesting after removing the wax, some of the failures attributed to wax in the ears may have been partly due to middle ear disease. Finally the child was tested with a pure tone audiometer by air and bone conduction for hearing acuity over the auditory spectrum. In this way the amount and the location of the defect to the middle or inner ear could be determined. The authors report their observations on about 1,000 children with good social conditions and on about 6,000 children with poor social conditions. It was impossible to test all the children in both summer and winter. The authors found that housing was of no significance, since even the children in the poor groups were well housed (orphanages). The two series of children did, however, differ greatly in the food they obtained. Middle-ear disease is about four times as common, on the average, under poor social conditions as it is under good social conditions; in the poorest places, whether urban or institutional, it may be nearly ten times as common as in a good environment, nearly a quarter of the child population being affected. Climate, housing and the mixing of children seem to have little effect on the incidence of the disease. The children with the highest incidence of defec-

tive hearing had diets deficient in many factors, but an increase in the food taken by two groups of these children for a year did not reduce the incidence of defective hearing. The figures here given show that probably the most important work on the prevention of deafness will be done by those who are striving to improve the social conditions and, in particular, the nutrition.

*Virus of Venereal Lymphogranuloma Obtained by Tissue Culture: Culture on Various Mouse Organs and Virulence Tests in Mice. K. Manabe.—p. 333.

*Id.: Development in Cells and Morphology of Virus. K. Manabe.—p. 355.

Studies on Elementary Body of Polyhedral Disease of Silkworm. T. Taniguchi, M. Asano, M. Hosokawa and K. Ishikawa.—p. 363.

Large Scale Cultivation in Vitro of Vaccinia Virus by Aeration of Medium. H. Yaoi and S. Arakawa.—p. 369.

Virus of Venereal Lymphogranuloma.—According to Manabe the so-called Miyagawa bodies after many investigations were identified as the virus of venereal lymphogranuloma. All other investigators who studied these bodies were able to identify them only after staining, but Manabe has been able to observe them also in the fresh living state. He presents two reports, the first dealing with the culture of the virus on various mouse organs and with tests on the virulence and the second dealing with the development of the virus in the cell and with its morphology. He used a modified cover glass method. The plasma was obtained from guinea pigs; the organ extract was prepared from brain, spleen and testes of adult mice, and the organs used for the virus culture were obtained from mice fetuses or from newborn mice. The virus strains to be examined were from the glands of patients whose disorder had been definitely identified as venereal lymphogranuloma. These strains are inoculated into mice. The diseased mouse brain is removed and immediately emulsified with Tyrode's solution (stock emulsion). Several pieces of organs are dipped into this stock emulsion and then are cultured (virus-tissue culture). Regarding his technic of culture, the author says that plasma and organ extract are mixed on the cover glass; the infected pieces of organ tissue are placed in this, and after organ extract is dropped on the tissues the preparation is sealed with paraffin and placed in the incubator at 37 C. Pieces of organs which are dipped for thirty minutes into an emulsion of healthy mouse brains serve as controls. Since it is not sufficient to identify the virus in the tissue culture, animal tests were made to determine the virulence. The studies revealed that the virus of venereal lymphogranuloma can be cultured in various organs from mouse fetuses or newborn mice. The virus develops with equal advantage in epithelial cells and in fibroblasts. Usually a vacuole is formed, which is filled with virus bodies. These bodies increase for four or five days, and then they decrease with the degeneration of the culture tissue. Their virulence increases as their numbers increase and decreases as the culture tissue degenerates. In his second report the author demonstrates that by means of dark field and oil immersion devices it is possible to observe the living virus and its morphologic development in the cell. Comparing stained specimens with living specimens, in which the virus bodies show motility, one can see that the virus of venereal lymphogranuloma develops and gradually increases in the living cell. Finally it breaks through the cell and repeats this process of development in another living cell. The individual virus bodies are readily differentiable. Occasionally two go together in the manner of diplocoeci, and again several are grouped together. Like Miyagawa and others, Manabe was able to observe differences in the size of the virus bodies.

*Investigations of Adrenal Insufficiency: Effect of Diet, Vitamins and Certain Other Factors on Survival of Adrenalectomized Rats. W. Weslaw and A. Wroblewski.—p. 1384.

Adrenal Insufficiency in Rats.—Weslaw and Wroblewski report the results of dietetic, vitamin and chemical experiments made on 172 white rats on which adrenalectomy had been performed. Male and female rats weighing from 100 to 330 Gm. were used. Recovery after the operation was rapid and left no lesions. The basic diet consisted of equal parts of cheese and barley and of milk. Brewers' yeast and cod liver oil were administered in specified quantities twice a week and occasionally carrots. The experiments were made in twelve series. The control group of forty rats, representing the entire range of the weight scale, was given the basic diet and showed a mortality of 95 per cent from three to twelve days after operation. Since the investigations were undertaken in part to verify the results of tests made by others with regard to survival medication in renal insufficiency, the negative and positive results of their own tests are carefully presented. No satisfactory results were obtained from the use of lactoflavin-5'-phosphoric acid on eighteen rats or on five other rats in which vitamin C was superadded. Cystine and glutathione employed on ten rats and sodium chloride as well as sodium chloride with sodium bicarbonate employed on other groups were equally unable to prevent loss of weight and vitality and death. Positive results were obtained on seven female rats to whose basic diet rye bread was added immediately after the surgical operation; furthermore, in an experiment with five male rats the basic diet was replaced by wheat bread, vitamin C and cod liver oil. The most remarkable results, according to the authors, were achieved with a regimen consisting of fresh wheat bread, thinly greased with lard, and cheese (Tilsitt). Repeated experiments showed that the loss of weight and the signs of renal insufficiency evolving from the basic diet were invariably and immediately arrested by the addition of wheat bread, lard and cheese and invariably reappeared when this addition was withdrawn. It insured survival for more than 100 days. Sodium chloride added to the milk was of no avail in the absence of the triple combination of wheat bread, lard and cheese, nor was potassium chloride in conjunction with wheat bread, lard and cheese. On the contrary, gain of weight was at once stimulated by the omission of sodium chloride. In another group the mere addition of the cheese, without bread, invariably induced vital restoration and caused the symptoms of adrenal insufficiency to disappear. The authors point out that though rye and wheat bread prolonged the life of the adrenalectomized rats from thirty to forty days, respectively, if given at once after the operation, the former in conjunction with the basic diet, the latter without, these regimens could not prevent death. They also assert that cheese by itself gave practically the same results as the rye bread-lard-cheese combination and may be the enigmatic energizing agent.

Vitamin C in Addison's Disease.—Pojer discusses the relationship between vitamin C and the hormone of the adrenal cortex and also the disturbances in the mineral metabolism during Addison's disease. Assuming a synergism of the cortical hormone and of vitamin C in the human organism and an impairment of this synergism in patients with Addison's disease, the author carefully observed the course of two cases of Addison's disease in which he administered large doses of vitamin C. He was induced to try this vitamin C therapy by a report of Laederich and his associates, who found vitamin C highly effective in a case of Addison's disease which had failed to respond to endocrine therapy and to the administration of sodium chloride. The two cases of Addison's disease in which

Pojer tried vitamin C therapy concerned a man aged 26 and a girl aged 14. In both cases it was possible to detect a vitamin C deficit in the urine. However, after four days of treatment with vitamin C the urinary deficit had disappeared. Patients were given daily twenty tablets (each containing 0.05 Gm.) of a vitamin C preparation; that is, the daily dose was 1 Gm. This medication caused changes in the mineral metabolism, as was indicated by the potassium, sodium and chlorine ions. For a time previous to the onset of the vitamin C therapy the patients had been given 15 Gm. of sodium chloride daily. In both patients the potassium content was increased, the sodium content was reduced, but the chloride content was normal. As a result of the vitamin C therapy, the general condition improved and the cutaneous pigmentation was reduced. In the patient who had been given daily 4 cc. of adrenal cortex extract by intravenous injection, the adynamia was reduced. The author concludes that the great improvement in the patients and the reduction in the pigmentation justify the use of vitamin C in Addison's disease.

- *Testosterone Propionate in Treatment of Acute Puerperal Mastitis. F. Guercio.—p. 353.
Quinine-Calcium Treatment in Inertia of Uterus with Early Rupture of Membranes. P. Cattaneo.—p. 415.

Testosterone Propionate in Puerperal Mastitis.—Guercio employed testosterone propionate in four cases of acute puerperal mastitis and in one case of chronic mastitis with postoperative lacteal fistula. The patients with acute mastitis stopped lactation as soon as the breast became painful, red and tumefacted. Although the condition was acute in all cases, none of the patients had an abscess when the treatment began. In the only case in the group in which the condition was observed from its onset, a daily dose of 0.01 Gm. of testosterone propionate was administered. The condition rapidly progressed to abscess formation, which was successfully treated by incision and drainage. Three patients were seen within one week from the beginning of the condition. They received a daily dose of from 0.05 to 0.07 Gm. of the substance, up to a total dose of 0.25 Gm. (in four days) or else 0.3 Gm. (in one week). In all cases pain, inflammation and tension of the breast were immediately relieved. In two cases the engorgement rapidly disappeared with consequent disappearance of fever and of the local infiltration. The improvement was moderate in one case of this group, in which mastitis was of the interstitial type. The condition evolved to abscess formation, which was successfully treated by incision and drainage. The patient who was suffering from chronic mastitis and lacteal fistula had a daily dose of 0.05 Gm. of testosterone propionate for four days. The secretion rapidly diminished. The fistula healed in about ten days. In all cases reported lactation could not be resumed. According to the author the treatment gives satisfactory results if it is given early in the development of acute mastitis and with high doses (from 0.05 to 0.07 Gm. a day up to a total dose of 0.25 Gm. in four days or 0.3 Gm. in one week). Duration of the treatment depends on its effects, as shown by the favorable evolution of the condition. However, because of the fact that high doses inhibit milk secretion, the author advises further work on the subject in order to find the proper dosage by which mastitis can be controlled without causing this inhibition.

- *Surgical Treatment of Stubborn Neuralgia of Bladder. E. Crispolti.—p. 521.
Microscopic Changes of Islands of Langerhans in Some Experimental Conditions (Administration of Dextrose and Insulin). T. Meneghini.—p. 539.

Stubborn Neuralgia of Bladder.—Continuous and persistent pain is the predominant symptom of vesical neuralgia, Crispolti says. It is associated with tenesmus and moderate dysuria. The urine is clear. The symptoms are not related to menstruation. They simulate those of appendicitis, acute abdominal conditions and diseases of the kidney or of the gall-bladder. There is no anatomic lesion in or around the urinary tract which can be considered responsible for the condition,

which is due to neuritis of the pelvico-abdominal sympathetic plexus. The author points out the utility of Cotte's operation, as modified by Pieri, in the treatment of the condition. The modified operation consists in removing the upper hypogastric plexus and making an exeresis of the lateral sympathetic chains of the first sacral segment. The author reports satisfactory results from the modified operation in two cases. The condition dated back several years in each case. The patients were in a general nervous state. They had had various operations because of erroneous diagnoses (appendectomy and nephropexy). Removal of the upper hypogastric plexus and exeresis of the lateral sympathetic chains of the first sacral segment were followed in both cases by immediate and complete disappearance of pain and of all symptoms, control of the dysfunction of the bladder and disappearance of the nervous condition. The satisfactory results have lasted in the two cases up to the present (almost one year after the operation).

Change of Blood in Fractures. G. di Castro.—p. 309.

- *Pulmonary Tuberculosis and Menstrual Disorders in Puberal Girls. I. Pedrini.—p. 332.

Menstrual Disorders in Pulmonary Tuberculosis.—Pedrini discusses the frequency and clinical significance of menstrual disorders in puberal girls suffering from pulmonary tuberculosis. He observed sixty puberal patients. In a group of fifty-five patients who were suffering from the disease in evolution, forty-four patients complained of menstrual disorders. Amenorrhea existed in thirty-two. The author found that amenorrhea takes place coincidentally with either the development or the aggravation of pulmonary tuberculosis. He believes that its presence is of value first for the diagnosis of pulmonary tuberculosis (when such a diagnosis has not previously been made) and second for ascertaining the evolution of the disease (after a diagnosis has been made). Amenorrhea in pulmonary tuberculosis is secondary to the condition of the lung. It is not related to local conditions of the internal genitalia, which are normal, and it is the manifestation of an organic reaction of defense. Moreover, any treatment which is directed to induce the return of menstruation in the course of the disease is unjustified, erroneous and harmful.

- Primary Chronic Polyarthritides: Etiopathogenesis. A. Robecchi.—p. 145.
*Transient Fever of the Newborn. A. Taddei.—p. 223.

Transient Fever of the Newborn.—Taddei noted the behavior of the rectal temperature during the first week of life of 152 infants of both sexes born in the Clinica Ostetrica e Ginecologica di Pisa. The infants were placed in three different groups, being allowed to nurse fifteen or forty-eight hours after birth and fasting or twenty-four hours after birth but fed during the day with a total quantity of 80 cc. of a 4 per cent solution of dextrose administered in small portions. The temperature was taken every three hours, day and night. The author found that the rectal temperature of the infant is different from that of the mother (and also of a twin in case there is one). Three hours after birth it diminishes, but in the course of the first day of life it rises again. Noticeable changes occur as a rule by the third day and disappear by the seventh or eighth day of life. The changes may be of any of the following types: (1) transient fever, (2) moderate fever and (3) hypothermia. The alterations of temperature in newly born infants are not associated with the interval between birth and nursing, fasting, the administration of dextrose solution, the more or less intense turgor of the mother's breast, the appearance of fever with milk secretion or of nonpuerperal fever in the first week of puerperium. The results of observations do not support certain etiologic theories of transient fever, especially those which show dehydration of the infant or the passage of toxic substances from the mother to the infant through the milk as causal factors. According to the author there is a physiologic congenital lability of the system of regulation of the body temperature in infants. Changes of the body temperature occur when the lability is associated either with

stimulation of the cerebral thermoregulating centers by disintegrated proteins which are absorbed by the infant's body (the so-called tumor from birth) or with a disequilibrium of hormones from structures which take part in the regulation of body temperature, such as the thyroids, the adrenals and the hypophysis.

Vitamin C Loss in Fever.—Hausberger and Neuenschwander-Lemmer record their clinical observations of the behavior of vitamin C in the blood plasma of febrile patients (pneumonia, sepsis, pyelitis), an outgrowth of research studies on the connection between vitamin C and the redox potentiality of the blood and organs in animals and in both healthy and febrile persons. They describe the method employed to determine the vitamin C content and the results of preliminary tests on normal controls. They found that intravenous injections of 10 mg. per kilogram of body weight of ascorbic acid measured at regular intervals were succeeded by a steady diminution of vitamin C in the blood, irrespective of whether the original vitamin C level was high or low. Five minutes after injection, on the average, only 5.4 mg. per hundred cubic centimeters was detected in the blood and after twenty-four hours only 0.48 mg. This diminution may be due to the action of the kidneys (after a lapse of two and one-half hours, 324 mg. of injected ascorbic acid was found in the urine out of 700 mg. administered, the blood level reaching a low value of 1.33 mg. per hundred cubic centimeters), or to the oxidation of the acid or to the rapid absorption by the tissues (the presence of ascorbic acid was observed electrometrically in the nonvascular epidermis two minutes after injection). The analysis of similar doses administered to febrile persons indicated a vitamin C loss in the blood level 24 per cent below that of healthy persons, a 4.1 mg. per hundred cubic centimeter loss on the average. After two and one-half hours the vitamin C blood level was often similar to that preceding injection. The confirmatory evidence of the urine showed that whereas healthy persons excreted as much as 50 per cent within the first hour, febrile patients voided only 15 per cent (78 to 100 mg. out of 600 to 650 mg. injected). The authors attribute this loss of vitamin C to its rapid disintegration in the blood or to tissular absorption. An accelerated vitamin C decomposition in the blood of febrile persons is attested by the fact that while ascorbic acid administered to healthy persons undergoes oxidation slowly, a larger proportion of the amount administered to febrile persons disappears within the same time limits. The same vitamin C impairment was observed by the authors in two cases of artificial fever and one of degeneration of the cardiac muscle. On the other hand, febrile persons subjected for a longer time to vitamin C dosage before the blood level test was made reacted to the test in the same way as healthy persons. The authors are in accord with the view that infectious diseases continuing for some time involve a heightened vitamin C loss and, in consequence, necessitate a heightened vitamin C regimen.

Early Treatment of Mastitis. A. Poerschke.—p. 1197.

Prophylaxis of Measles.—Grod first reviews experiences with convalescent serum and with serum from adults and then discusses the use of a mixed serum obtained from retroplacental blood. He employed the latter serum in the course of an epidemic of measles. It was administered to 170 children

in doses of from 15 to 20 cc. In the majority of children the serum was injected on the fourth or fifth day of incubation; that is, at the time when the exanthem appeared. To eight children it was given earlier and to three not until the sixth day of incubation. After excluding the cases in which exposure to measles was not absolutely certain and also those which had not been observed for a sufficient length of time, there remained forty-four cases which were suitable for the evaluation of the efficacy of the serum made from retroplacental blood. In 47.7 per cent of these cases complete protection could be obtained, in 36.3 per cent the severity of the disease was noticeably weakened and in 16 per cent it was not influenced. The author points out that these figures correspond to those obtained with serum from adults. The serum from retroplacental blood was well tolerated by the children. Placental extract, when given under the same conditions and in identical doses, was found to have the same therapeutic effect but was not so well tolerated as the serum from retroplacental blood.

*Evaluation and Treatment of Incontinentia Alvi During Childhood. H. Oegg.—p. 230.

Incontinence of Feces in Children.—Oegg gives detailed clinical histories of three children with incontinentia alvi. The first patient was a boy of almost 9 years and the two others were boys of about 6 years. The author is convinced that functional nervous factors on a psychogenic basis played an important part in the development of the incontinentia alvi, as all of these children lived in an environment that was unfavorable for their psychic as well as physical welfare. After thorough evacuation of the bowel, psychotherapy together with dietetic measures produced cure within a comparatively short time in all three cases. X-ray examination following a barium sulfate enema revealed in all changes in the large intestine. Dilatation was noticeable not only in the region of the ampulla and of the sigma but also in the colon. X-ray examinations of the hand were made for two of the children, and in both of these the bones showed pathologic changes. The diet had been unsuitable in all three of the children. The author assumes that the unsuitable diet produced intestinal changes, which played a part in the pathogenesis of the incontinentia alvi. This assumption becomes even more probable when it is considered that the bones likewise exhibit changes indicative of former malnutrition. The author thinks that the changes in the colon are probably the result of changes in the tonus and motility of the colonic musculature, which in turn are caused by disturbances in the sympathetic nervous system. Although hereditary and mental factors may be the basis, the author is convinced that unsuitable nutrition is the factor that leads to the manifestation of the incontinence of feces.

Differential Diagnosis of Spondylitis Infectiosa.—Bade shows that spondylitis infectiosa occurs after many different infectious diseases such as scarlet fever, measles, smallpox, influenza, malaria and typhus, after infections with pneumococci, staphylococci and streptococci, and after brucellosis. He reports

ten cases of spondylitis infectiosa. He regards as characteristic a narrowing of the involved intervertebral disk. This narrowing generally does not involve the entire intervertebral disk but frequently only a sector or a half. The adjoining portions of the diseased vertebrae show small irregularities and defects and a more dense structure. In the reported cases the fine osseous foci developed as a rule only after the narrowing of the intervertebral disk. Especially typical for infectious spondylitis is the rapid appearance of reactive proliferations of bone which develop into marginal pads and bridging bands. The differentiation of spondylitis infectiosa from osteomyelitis of the spinal column is easy in the severe acute cases, which often terminate in death before the changes become roentgenologically demonstrable. Subacute and chronic cases of osteomyelitis with sclerosis of the involved vertebra are differentiable from spondylitis infectiosa by roentgenoscopy, as are also those cases in which the roentgenogram discloses areas of fused bone tissue. However, there are chronic cases of osteomyelitis in which the roentgenogram discloses the same narrowing of the intravertebral cleft and the small defects on the terminal plates of the vertebrae as is the case in spondylitis infectiosa and thus a differentiation merely on the basis of the roentgenogram is impossible. The differentiation from tuberculosis of the vertebral column is usually readily accomplished merely on the basis of the x-ray examination. But in the cases in which the roentgenogram is not sufficient for this purpose, the clinical aspects and especially the course will permit a diagnostic decision. In difficult cases, specimens of pus should be inoculated into guinea pigs. It should be remembered that even in spondylitis infectiosa gravitation abscesses may develop, although they are less frequent than in tuberculosis and osteomyelitis of the vertebral column. Another disorder that must be considered in the differential diagnosis is osteochondrosis of the intervertebral disks. This degenerative disease also causes narrowing of the intervertebral disks and sclerosis of the adjacent portions of the bodies of the vertebrae, that is, a picture develops which greatly resembles the terminal stages of spondylitis infectiosa. However, in osteochondrosis the narrowing is uniform throughout the intervertebral disk, defects of the terminal plates are absent and loosening of the structure of the intervertebral disk may cause dislocation of adjoining vertebral bodies.

Practical Significance of Serologic Examination, Especially of Complement Fixation Reaction, for Diagnosis of Weil's Disease. W. Gaetgens.—p. 287.

Immunity in Venereal Lymphogranuloma.—Caminopetros tested several series of patients who had adenitis or rectitis by the injection of antigen or of virus into the glandular tissue and into the rectal mucosa or the perianal vegetations. These tests were always complemented by the inoculation of virus and by the search for virus-neutralizing substances in the serum of the patients. Further he investigated whether the specific antigen injected into the vein or under the skin of new subjects, several times a week and for a long period, would provoke the appearance of virus-neutralizing substances in the blood or cutaneous allergy and whether by this procedure the organism could be protected against experimental infection. At the same time he investigated, on the one hand, the preventive action of the serum of convalescents against experimental infection of rabbits and, on the other hand, the curative action of such a serum in cases of rectitis or adenitis. On the basis of his observations, the author concludes that in venereal lymphogranuloma each receptive tissue possesses a reactivity to the infection which is peculiar to it and which determines the characteristics and the evolution of the infection: cure of adenitis in from six to eight months, extremely long persistence of rectitis, and rarity of lesions in the female genitalia in spite of the long

persistence of the virus. The general immunity conferred on the organism by adenitis as well as by rectitis has no influence whatever on the local infection. This immunity, which is manifested by the cutaneous allergic reaction and the refractory state of other receptive tissues (groups of glands) distant from the focus of infection, must be attributed to the direct action on these tissues of the virus circulating in the blood at the onset of the infection. On the other hand, the injection of antigen (several times each week over a long period) can produce neither the appearance of a general refractory state nor cutaneous allergic reaction and cannot protect the organism against experimental infection. In the search for virus-neutralizing substances in the blood, it was found that the threshold was extremely low in rectitis as well as in old cases of adenitis even after inoculation of virus or of antigen. The seroflocculation is not as clearly positive as during the period of inguinal infection. Furthermore, the serum of patients in whom the disorder has existed for a long time has no prophylactic action against experimental infection in rabbits. Such serum seems to have no influence on the evolution of adenitis or rectitis. On the other hand, the injection of antigen into the diseased tissues of adenitis or rectitis exerts a noticeable curative action and can be used in their treatment.

*Blood Transfusion in Extensive Burns. V. I. Struchkov.—p. 53.

Complications of Spinal Anesthesia.—Egorova reports 128 cases in which operation was performed under spinal anesthesia in the gynecologic and surgical services of the Moscow Clinical Institute. These patients did not present any lesion of the nervous system prior to the operation; 35.7 per cent were free from any complication after the spinal anesthesia, while 64.3 per cent presented a variety of symptoms pointing to the irritation of the meninges. Of these, 10 per cent had a mild transient headache, 13.5 had a headache combined with nausea and vomiting and occasional occipital rigidity and 24.3 per cent had headaches accompanied by a meningeal symptom complex. Syncope took place in 2.4 per cent, involvement of cranial nerves in 3.2 per cent, sphincter disturbances in 13.8 per cent, diminution or loss of tendon reflexes in 15.6 per cent, paresis of the lower extremities in 4.6 per cent and trophic lesions of the skin in six cases. The duration of the symptoms varied from a few days to several weeks, and in a few cases with involvement of the conus caudae from several months to years. The author concludes that the clinical reaction of the human organism to the introduction of anesthetizing substances into the subarachnoid space is of the meningeal type, with occasionally deeper involvement of the brain substance and the roots. These complications were not associated with preexisting nervous lesions. Microscopic studies of a patient dying eighteen hours after gastric resection, from a hemorrhage, revealed the presence of definite leptomeningitis and epiduritis of the spinal cord. The author concludes that spinal anesthesia cannot be regarded as entirely safe and its complications as innocent. The indications and contraindications for its use must therefore be carefully weighed.

Blood Transfusion in Extensive Burns.—Struchkov reports 242 cases of extensive burns treated by the open method. Thirty-seven of the patients presenting shock, grave sepsis or retarded healing were given one or more blood transfusions. The age of the patients varied from 6 months to 63 years. There were nineteen children. The mortality rate in the children's group was 10.5 per cent, whereas among the children treated without blood transfusion it was 19 per cent. Eight patients were given transfusions while in a state of shock. All of these recovered. Of the twenty-four given transfusions during the suppurative septic stage, a striking improvement was noted in twelve, a satisfactory result in eight and no effect in four. In two of the latter conserved blood from nephritic patients was used. Transfusion of fresh citrated blood during the septic

suppurative state had the effect of removing the toxic manifestations. The temperature sharply declined, the appetite improved, and the patients felt stronger and began to gain weight.

Hematuria and Renal Calculi After Sulfapyridine.—Snapper and his associates describe four cases of hematuria after treatment with sulfapyridine. In the first patient, a man aged 35, and in the fourth patient, a child aged 22 months, the hematuria developed without local symptoms. In the second patient, a youth aged 19, the hematuria was accompanied by renal colics, which were apparently caused by dilatation and spasm of the left pelvis and ureter. The probable cause of the hematuria and pain was precipitation of acetylsulfapyridine crystals in the urinary passages, as was confirmed by the post-mortem examination in the fatal (third) case. In this case, the treatment with sulfapyridine caused hematuria but no renal colics. The necropsy revealed a small calculus in the renal pelvis. Examination disclosed that the calculus consisted of a compound of sulfapyridine, probably acetylsulfapyridine.

Aspiration Biopsy of Liver.—Iversen and Roholm developed a method of aspiration biopsy of the liver by which an amount of tissue sufficient for microscopic examination is obtained. They use a simple trocar consisting of a cannula 18 cm. long and 2 mm. wide and a pointed stylet. The free edge of the cannula is sharp and notched. By turning the cannula on its axis, while it is pushed into the liver, a cutting effect is obtained. The authors introduce the cannula in the posterior axillary line in the ninth intercostal space, just below the lower arch of the last digitation of the serratus anterior, thus passing through the complementary pleural space and the diaphragm before reaching the liver. Before the aspiration, the skin is painted with iodine and anesthesia is produced with a 2 per cent solution of procaine hydrochloride with epinephrine. The anesthesia is effective within two minutes; this interval is used to teach the patient to hold his breath after deep expiration. After the skin is pierced the trocar is pushed in till its tip meets the upper surface of the diaphragm, which moves in breathing. The trocar is then withdrawn a little so that it is clear of the diaphragm. The patient is told to breathe deeply about four times, stopping with deep expiration and fixation of the chest. The last part of the procedure should be carried out quickly, but it should not be commenced before expiration is completed. The trocar is pushed through the diaphragm and into the liver for about 2 cm. The stylet is withdrawn and a record syringe (10 cc.) is attached to the cannula. A vacuum is produced by pulling the piston as far back as possible; the cannula is forced from 1 to 2 cm. into the liver, while the syringe is rotated at the same time. The cannula is quickly withdrawn, and the operation is complete. The authors resorted to this form of biopsy 160 times. It proved successful in 22.5 per cent of the cases. The method involves little inconvenience for the patient, but the risks involved are still somewhat uncertain. For this reason,

the indications for its employment cannot be definitely decided as yet. Tendency to bleeding is a contraindication. The method makes it possible to demonstrate the presence of acute and chronic inflammatory conditions, tumors, degenerative processes, obstruction to the flow of bile and other conditions. The method is helpful not only in the diagnosis but also in the prognosis.

Influence of Vomiting and Nausea on Renal Function.

—In the course of tests on the renal function Clausen occasionally noticed an essential shift in the ratio of urea clearance to creatinine clearance in direct connection with nausea and vomiting, and so he decided to investigate this problem. He cites experiments which demonstrate that medicamentous or mechanical production of nausea and vomiting gives rise to considerable changes in the function of the kidneys. Nausea and vomiting diminish the renal function, and this decrease does not affect the excretion of all substances equally, urea clearance being lowered relatively more than creatinine clearance. This lowering of the renal function is not dependent on changes in the blood pressure, as no decrease of the blood pressure was found during the periods in which the renal function was lowered. The decrease in the renal function coincides with a pronounced decrease in the diuresis. Although this decrease in diuresis may by itself result in falling clearance values, it will influence the urea clearance and the creatinine clearance in the same manner, so that it cannot be the cause of the observed fall in the urea-creatinine clearance ratio. Nevertheless, the author thinks that the abrupt fall in diuresis contributes in some way to produce this fall in the ratio. He thinks that the decrease in creatinine clearance and urea clearance may be due either to changes in the glomerular filtration (due to local circulatory disturbances) or to changes in the activity of the tubular cells, whereas the shift in the ratio between urea clearance and creatinine clearance can be explained only by an increased reabsorption of urea in the tubules of the kidney. The author concludes that these studies are of practical significance as they indicate that caution is necessary in the evaluation of tests of the renal function if nausea and vomiting appear while the tests are being carried out.

Sugar Metabolism After Carbon Monoxide Poisoning.

—The fact that glycosuria is observed after carbon monoxide poisoning induced Moeschlin to examine the sugar content of blood and urine and the diastase content of the urine in all cases of acute carbon monoxide poisoning. In some of these cases he also investigated the sugar content of the cerebrospinal fluid and the course of the blood sugar curve during tolerance tests. He made his investigations in thirty-five cases of acute carbon monoxide poisoning, excluding all cases in which there were no definite signs of intoxication and those in which more than twenty-four hours had elapsed since the intoxication. In 57 per cent of the cases the blood sugar was noticeably increased following the intoxication. The increase in the blood sugar content generally persisted for from twenty-four to forty-eight hours, but in two cases it persisted three days and in one case eight days. The previous existence of a diabetic component was definitely excluded by later tests. There was no parallelism between the severity of the intoxication and the degree of increase in the sugar content of the blood; however, the incidence of hyperglycemia was greater with severe than with mild intoxication. Glycosuria was observed in only 17 per cent of the cases. The sugar content of the cerebrospinal fluid proved noticeably increased in eight of eleven cases. The diastase content of the urine was not increased after carbon monoxide poisoning. The most interesting changes were observed in the blood sugar curves, the majority of which were pathologic. Some had the typical diabetic outline, with steep increase in the blood sugar, absence of a double peak and retarded decrease, whereas others had a steep and high increase with a comparatively rapid decrease. Repeated control tests revealed that the changes decreased rapidly, so that after a few days or a week normal curves were seen. The author was able to corroborate the appearance of leukocytosis following acute carbon monoxide poisoning, and he found that this leukocytosis is more frequent than hyperglycemia. He believes that the disturbances in the sugar regulation are caused by a central impairment, but he is unable to decide whether this impairment is due to the direct toxic action of the carbon monoxide or to hypoxemia.

LOW BACK PAIN

CORRELATION OF SOME OF THE SIGNS AND SYMPTOMS

JOSEPH A. FREIBERG, M.D.
CINCINNATI

During the past five years especially, great strides have been made toward a clearer understanding of the protean causes of low back pain. With this broader knowledge, contributed to by many orthopedic surgeons and neurosurgeons, the accurate diagnosis of low back pain has become most complicated. It has not been many years since the differential diagnosis rested only between a lumbosacral or a sacro-iliac lesion as the cause of both low back pain and so-called sciatica. Many of those who studied the problem from day to day and year to year were of the impression that they understood the subject completely, only to run up against a blank wall of misunderstanding at too frequent intervals. Many orthopedic surgeons believed that the problem was simple and that it was merely a question of differentiation between lesions in the two regions, lumbosacral area versus sacro-iliac joints. The fact that there were many signs and symptoms common to the two lesions was known but not fully appreciated. The fact that the lumbosacral protagonists cured a large proportion of their patients, as did also the sacro-iliac exponents, was a constant source of forensic debate. Now one is able to appreciate, to a certain extent, why neither school of thought was completely convincing: because there was actually a third lesion, the herniated or protruded intervertebral disk, then unrecognized in its frequent role as a cause of low back pain and sciatica. Today we see this herniated disk lesion invested with tremendous responsibilities—possibly too great responsibilities. Though this pathologic lesion is a definite, proved clinical entity and its recognition and removal have cured many patients, one must not become overzealous and believe that this lesion alone is responsible for the majority of cases of low back pain, with or without sciatic pain.

At the same time that the herniated disk syndrome has become better known, so also have the intricate and less obvious muscular and fascial lesions about the lower part of the back, pelvis and thigh yielded to clinical and scientific study. Physicians are faced now with many more functional and organic causes for the acute and the chronic low back pain and with a much greater differential diagnostic problem. Likewise, as the surgical procedures developed to attack these several newer lesions are accompanied by relatively little danger to the

general health and life of the patient, surgery has assumed an even more common means of treating the many who suffer pain in the back. The proponents of the several newer surgical procedures for the relief of such pain have sounded many warnings and admonitions regarding the too free use of these operations, but what orthopedic surgeon has not seen patients with the back pain or sciatica still present after one, two or three operations. The last operation is usually successful, but could not the previous one or two have been avoided? Again, have conservative means, such as postural training, traction, manipulation, physical therapy and braces, been used intelligently before surgical attack has been carried out? In many cases early surgical treatment is to the great advantage of the patient, but in other series careful study of the individual patient will show that nonsurgical therapy alone is indicated in from 80 to 90 per cent of the cases.

In this discussion the infectious lesions capable of causing low back pain have been excluded because, in general, they are more readily recognized, and when recognized the therapy is well indicated. Suffice it to say that an active infectious lesion is treated conservatively and that a painful or unstable joint due to a pre-existing infectious process must be immobilized either by muscular or mechanical support or by operative fixation.

DIAGNOSIS

The real diagnostic problem in low back pain, with or without sciatica, is to differentiate between the primary and secondary causes for the pain and to evaluate their relative significance with regard to therapy. There are several conditions in which treatment of the secondary lesion alone relieves the pain temporarily, and even permanently, but when this plan of therapy is relied on it must be used knowingly. In the lower part of the back there are numerous true joints: those between the lumbar articular processes and the sacro-iliac joints. Traumatic or infectious processes involving one or more of these joints is accompanied by an involuntary muscle splinting or muscle spasm, response similar to that associated with lesions in other joints in the body. This muscle spasm associated with low back lesions may involve one or more muscle groups of the spine, pelvis or thigh. Dissimilar lesions may be and are associated with similar types of muscle spasm responses. Therefore the clinical picture of the so-called sciatic scoliosis, with limitation of normal mobility of the lumbosacral joints and restriction of the straight leg-raising test, cannot be indicative of any one lesion. Likewise, as the muscle spasm, per se, may be painful or may cause secondary painful areas, it is frequently difficult to differentiate between the primary lesion causing the muscle spasm and the secondary lesion, which is sometimes the true cause of the pain. It is this situation, peculiar to the low back lesions, which has caused the

Read before the Section on Orthopedic Surgery at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

confusion of diagnoses and therapeutic procedures. Add to this picture the rather frequent anomalies of structural development of the osseous tissues in the lumbosacral area, and the maze is complete.

The primary lesion associated with low back pain may be a true joint lesion, synovitis, a ligamentous trauma, periostitis at the site of muscle origin or insertion, myositis, fasciitis or a lesion of the intervertebral disk. The etiologic factor initiating the syndrome of back pain, with or without sciatica, may be a trauma disrupting the normal function of a joint, a ligamentous or periosteal tear associated with primary localized hemorrhage and secondary fibrous or scar tissue formation. It may be a gradual fascial or muscular contracture dependent primarily on faulty posture. In this last instance the faulty posture may be due to an osseous anomaly associated either with hypermobility and instability of the lumbosacral or fourth and fifth lumbar articulations or muscle imbalance dependent on some other cause, such as pregnancy with persisting relaxation of the abdominal muscles. The primary lesion in many cases is similar to lesions occurring commonly about other joints of the body but obscured because of the intricate mechanism involved in the lower part of the back. Furthermore, this joint or ligamentous lesion initiates a series of muscle responses which may be common to all of the different primary lesions.

Obviously, before an attempt is made to treat a syndrome involving low back pain the lesion must be identified. The history of the mode of onset is especially important. Was there a trauma and, if so, what was its nature? Have there been previous similar attacks, were they induced in a similar manner, and was leg pain or sciatica invariably present? Have the initial symptoms persisted, or did they disappear as new symptoms developed? In other words, in many cases the history will clearly bring out the fact that there was a single site of pain and tenderness, subsequently masked by the gradual development of secondary symptoms. The story of something slipping or snapping as a primary symptom should not be passed over lightly, as this sign usually indicates a ligamentous or periosteal tear which may well be the lesion to be treated. Postural strains, such as accompany automobile driving and faulty posture at a desk, frequently initiate a muscle imbalance causing an anomalous lumbosacral structure to become symptom producing. Equally important in the history is the fact that certain body positions or attitudes relieve the pain. Finally, the detailed history in the case of both acute and chronic backaches is just as important as in other bodily ailments.

On physical examination, the signs and symptoms associated with low backache may be numerous or few, depending on the individual case. The acute low back pain with or without sciatic pain should be approached in a manner entirely different from that suited to the chronic case. Many of the acute cases of recent onset represent ligamentous, periosteal or muscular tears with associated local bleeding. An extensive physical examination accompanied by forceful testing of the range of mobility of the various joints is definitely contraindicated, as it is in the case of acute ankle or knee lesions. Manipulation under these circumstances will tend to aggravate the lesion and increase the degree of damage, although an existing painful muscle spasm may be temporarily relieved. Observation and palpation will elicit the location of the areas of tenderness and injury. Acute ligamentous, capsular and muscular lesions elsewhere in the body are treated by immobilization and

the control of local bleeding. Therefore, in similar lesions about the lower back region immobilization by adhesive strapping and bed rest, accompanied by cold compresses or ice bags, is similarly indicated for at least forty-eight hours. These soft tissue lesions require from seven to twenty-one days to heal; therefore supportive therapy should be pursued for this period. It is the failure to recognize the nature of these initial lesions which contributes toward many of the recurrences of symptoms and toward many of the secondary persisting ligamentous, fascial and muscular lesions seen in the chronic cases of low back pain. Inadequately treated ruptures of the internal lateral ligament of the knee joint result in an instability of the knee joint associated with recurrent episodes of pain, synovitis and muscular imbalance. Ligamentous tears healed by relatively wide bridges of cicatricial tissue result in elongated or contracted ligaments with a relative loss of elasticity. Untreated periosteal tears are followed by areas of organized subperiosteal hematomas and fibrous tissue infiltration. Similar sequelae develop in muscle lesions. The sites of these soft tissue lesions about the lower part of the back are fairly constant, as determined by areas of pain or, more reliably, by point tenderness on pressure.

The more severe low back injuries may be accompanied by lesser fractures involving articular processes, laminae or pedicles. The prompt recognition of a fracture involving the arcus of a vertebra and its subsequent immobilization will prevent many chronic complaints involving the lower part of the back. These fractures, although often isolated and small, are true fractures not only capable of producing symptoms but requiring from eight to ten weeks to heal. Nonunited, these lesions may offer sufficient local instability to be the basis of recurrent or constant pain.

The exact mechanism and degree of trauma preceding ruptures of the annulus fibrosus and consequent posterior protrusions of the intervertebral disks has not been definitely determined. Likewise, the less frequent lesions of the ligamentum flavum followed by hypertrophy or cicatricial thickening of the ligament are not clearly understood. That these lesions do occur and that they may be associated independently with constant or recurring attacks of low back pain with or without sciatic pain must be accepted. However, that these lesions occur and that in many cases reported by many authors complete recovery has followed laminectomy does not indicate that in all instances recovery or relief from symptoms depends solely on removal of the lesions. The functional mechanism of the lower part of the back is intricate and varies extensively with the functional demands placed on it; hence it is highly probable that more than one factor is responsible for the production of pain or dysfunction in many cases. Likewise, the elimination of one of two or more abnormal conditions in a given case may result in complete relief from symptoms and clinical recovery. From the very nature of the lesions at operation and the history of no recent injury, a protruded disk and a recent low back pain cannot always be correlated. Previous episodes of low back pain in a patient have been relieved by conservative therapy, but in a later, possibly more severe, attack a protruded disk has been discovered and removed. Was this disk the causative factor in the previous similar attack of back pain? An analogous situation may arise in the case of congenital bilateral pedicle defects of the fifth lumbar vertebra, entirely symptomless for twenty-five or more years, which are discovered associated with an attack of

low back pain with or without sciatic pain. The instability of the lumbosacral joint in this instance may be, and often is, a predisposing factor in the clinical picture; nevertheless, a certain number of these patients are cured or relieved by nonoperative therapy or by lesser operative procedures not actually involving the pedicle defects.

Some authors have reported rather large series of cases of sciatic pain, with and without low backache, entirely relieved by epidural injections, neurolysis of the sciatic nerve or injection of fluids into the sheath of the sciatic nerve. Obviously, without regard to the foregoing discussion it may be assumed that many conditions about the lower part of the back are capable of causing painful manifestations and that because of the intricate mechanism of this region no one type of lesion can be accepted as the chief etiologic factor. From one large orthopedic center the report has been made that from 80 to 90 per cent of the cases of low back pain are relieved by conservative measures. Possibly this estimate is somewhat high, but nevertheless there is too great a discrepancy between this percentage of nonsurgical cases and the figures from many smaller orthopedic centers.

SIGNS AND SYMPTOMS

Obviously, not all of the signs and symptoms associated with low back pain can be discussed in this paper. The following features, frequently encountered, are the bases for varied clinical conclusions:

The history of acute aggravation of pain in the lower part of the back, buttock or sciatic nerve area accompanying sneezing or coughing is often attributed to an increased intraspinal fluid pressure and is consequently considered an indication of a protruded disk or of other mechanical pressure on the nerve root. On the other hand, sneezing and coughing are closely linked with spasmodic contracture of the abdominal and back muscles. Lesions of the fasciae, muscles or joints may therefore be equally affected momentarily. Especially is this true of periosteal lesions.

So-called sciatic scoliosis with flattening or convexity of the lumbar spine may accompany any acute or subacute lesions of the lower part of the back and in itself is indicative only of an irritative lesion of the neuromuscular mechanism of this region.

Relief from pain and disappearance of muscle spasm on lying down generally imply that a postural or abnormal mechanical strain has been removed from a lumbosacral or sacro-iliac joint. Intraspinal lesions, protruded disks and hypertrophied ligamenta flava usually, although not constantly, are unaffected by changing of position such as lying down or sitting.

In the presence of muscle spasm or contracture of the gluteus maximus or hamstring muscles or both, limitation of forward bending in the standing position as compared with the sitting position has relatively little significance, as in standing the affected muscles are put on increased tension and in sitting they are relieved of this tension. In the absence of muscle spasm or contracture of these muscles, however, this test aids considerably in differentiating between lumbar and sacro-iliac or fascial lesions.

Limitation of passive lumbar flexion in the supine position signifies a lumbar or lumbosacral articular lesion.

The straight leg-raising or Lasègue test when definitely positive may be interpreted in several ways: Limitation of hip flexion with the knee extended may

be due to spasm of the gluteus maximus and hamstring muscles caused by lesions of these muscles or their periosteal origins, lesions of the sciatic nerve or its nerve roots, or articular lesions of the sacro-iliac or lumbosacral joints accompanied by muscle spasm. On the other hand, pain induced on one side only, regardless of which leg is tested, usually centers attention on the sacro-iliac joint of the painful side.

The Ober test for contracted thigh fascia may be positive as the result of muscle spasm involving the tensor fasciae femoris and gluteal muscles. When this test causes a localized pain, a periosteal lesion should be suspected. When the Ober test is positive during an interim between attacks of back pain it is really indicative of contracture of the fascia lata or of the iliotibial band.

The Ely, or prone knee flexion, test is one of the most valuable maneuvers to demonstrate the existence of thigh fascial contractures but not of a lumbosacral lesion, as originally described. In the first place, because of the position of the patient, spasms of the glutei and hamstrings play practically no role. If on passive flexion of the lower leg on the thigh the buttocks arch away from the table and at the same time the leg abducts at the hip joint, a true contracture of the anterior and lateral thigh fascia is demonstrated.

In the supine position with the knee extended, internal rotation of the leg followed by slight flexion of the hip and adduction of the leg may cause localized pain in the buttock. When associated with pain or pressure over the piriformis muscle, one of two lesions is indicated: either a lesion of the piriformis muscle or a lesion of the sciatic nerve or its sheath in the region of the piriformis muscle.

Again in the supine position, on passive twisting or rotation of the pelvis by forcing the flexed hip and knee of one side across the body while fixing the ipsilateral shoulder, limitation of motion on one side associated with pain suggests an articular or capsular lesion of the lumbosacral or sacro-iliac joint, depending on the site of the pain. Relief from symptoms following this manipulative test is especially dramatic in some instances.

Probably the most valuable of all the tests in determining the exact site of periosteal, ligamentous or joint lesions is the localization of one or more areas of definite tenderness on palpation when the patient is lying comfortably on a firm table. Unless a careful routine is carried out, the area of maximum tenderness may be missed. The most frequent points of tenderness may be found at the following sites:

1. The supraspinous ligament between the spinous processes.
2. The periosteal attachment of the erector spinae muscles to the dorsum of the sacrum.
3. The gluteus maximus and medius origins along the iliac tuberosities and crests.
4. The piriformis muscle, an area midway between the greater trochanter and the posterior-superior iliac spine.
5. The iliotibial tract or fascia lata over the greater trochanter and between the greater trochanter and the iliac crest.
6. The sacro-iliac notch or the posterior-inferior sacro-iliac ligaments.
7. The lumbar zygapophysial joints, about 1 inch lateral to the spinous processes.

If a single site of definite tenderness is found on palpation and the lesion is not of recent origin, the injection of a few cubic centimeters of 1 per cent procaine hydrochloride may relieve the pain temporarily.

or, less frequently, permanently. This relief of pain on injection of procaine hydrochloride usually demonstrates the fact that the lesion involves periosteal or ligamentous tissues previously the seat of a trauma or inflammatory process. If the injection is in the vicinity of a nerve such as the superior or inferior gluteal it may be argued that the pain stimulus is interrupted by temporary nerve block, but this explanation is not entirely satisfactory.

In this discussion of low back pain two important types of observation are not included, namely the complete neurologic and x-ray studies. Obviously, these examinations must be included. Suffice it to say that in both the spinal studies must be correlated with the other clinical data. A diminished or absent achilles tendon reflex does not always signify the existence of a protruded intervertebral disk, but this is often the case. Subjective numbness or sensation of coldness of the leg in the absence of disturbance of sensation does not indicate an essential sciatic nerve involvement. A neurologic examination will exclude central nervous system degenerative lesions or peripheral neuritis. When the general observations suggest an intraspinal lesion, lumbar puncture studies and, if indicated, visualization studies with iodized oil should be made. The x-ray examination must also be interpreted in the light of the purely clinical features, as some anomalous osseous lesions are the cause of low backache while others are proved to be merely coincidental.

The scope of this paper does not include a discussion of therapy. If an exact diagnosis can be made, the choice of treatment is usually obvious, and a plan of preliminary conservative therapy is suggested. The fasciotomy of Ober, the periosteal stripping of Heyman, the myotomy of the piriformis, laminectomy and fusion operations are all excellent procedures on the condition that they are carried out in carefully studied and selected cases. Contractured or permanently shortened fasciae and muscles should be stretched or cut, but fasciae and muscles under increased tension due to muscle spasm should be treated conservatively.

CONCLUSION

Any disturbance of the mechanical function of the lower part of the back may initiate somewhat similar combinations of signs and symptoms. Ligamentous, periosteal, muscular and fascial lesions may be identified by physical examination. Restriction of motion and tenderness to palpation remain as the most significant physical features. Initial conservative, nonoperative therapy serves a twofold purpose, as a valuable diagnostic aid and as a method of curing a large number of the patients.

ABSTRACT OF DISCUSSION

DR. PHILIP LEWIN, Chicago: I should like to emphasize conservatism, which can easily be changed when new facts are presented. We are in a state of evolution analogous to that in which we were concerning fracture of the neck of the femur a few years ago. I should like to place before you the analogy of what I term a double U, that is one U superimposed on an inverted U, which will help to visualize some aspects of the problem. The upper U consists chiefly of the erector spinae, the intervertebral disks and ligamentum flavum lesions, the lower U, chiefly the tensor fasciae latae, and lumbosacral and sacro-iliac joint, the piriformis and the coccygeus muscle. Each human leg is a fork of the theoretical U. The three points indicated are the lumbosacral and the sacro-iliac joints. The lower U is composed of the tensor fasciae latae, the sacro-iliac,

the lumbosacral joint, and the piriformis and the coccygeus muscles. When these are superimposed, one has the double U analogy. Any procedure that breaks the circuit may give, in certain selected cases, complete or partial relief. These procedures are chiefly injections, liberations, fusions and relief from pressures, such as following the operation for protrusion of the intervertebral disk and hypertrophied ligamentum flavum. One of the oldest complaints and observations with regard to backache is pain or stiffness or both on resuming activity after a period of rest. One need only to watch elderly persons arise from bridge or see a group of people get out of a bus after a long ride and observe the stiffness which appears on resuming activity. I have given it the name "postinertial dyskinesia." I should like to ask the facetious question Where do the intervertebral disks hide between attacks? Chamberlain and others have offered some plausible answers to this question. I should like to suggest the general use of the term "spondylogram" or "spinogram," like the cardiogram. I have found at operation in several cases fusion of the ligamentum flavum and the dura, which I call "ligamentothecosis" or adhesive ligamentothecitis. I believe that this lesion is definitely a trauma which may produce hemorrhage, some scarring, some more trauma, adhesions and, when the patient bends, especially forward or backward, there is a pull on the sheath and pressure on the nerve. I believe in some cases that produces pain.

DR. G. C. BATTALORA, New Orleans: There are probably no other diagnostic problems more complex than low back disorders. The difficulty is not lessened by the fact that several different conditions can give rise to a similar picture. I am going to dwell mainly on the so-called low back syndrome in which there are backache, sciatica, list of the spine to one side or the other, and positive leg signs, with absence of ankle jerks. Certain neurosurgeons rely exclusively on these manifestations in making a diagnosis of a disk lesion. The frequency with which one sees disk protrusions has struck me forcibly, in observing certain dissecting room preparations. I know well that the incidence of these protrusions does not parallel the incidence of disabling symptoms that certain patients complain of. If a patient has these symptoms and signs, with the ankle jerk absent, this absence of the ankle jerk may be due to pressure on the fourth or fifth lumbar nerve roots, either in the intraspinal spaces or perhaps outside, because of spasm in certain muscles. If one treats these cases conservatively, relieving the irritative lesions on the nerves, one can get a reestablishment of the reflexes; therefore, before making a diagnosis of a disk lesion one should exclude all other orthopedic problems.

DR. EARL D. MCBRIDE, Oklahoma City: A sign which I term the "cocked knee sign" has been puzzling to me with regard to its mechanics. It seems to be a characteristic sign in certain cases of muscle spasm associated with sciatic nerve involvement. The patient can sit erect when the knee on one side is flexed, but when both knees are flattened straight out on the table the patient has to lean backward and cannot bend forward. One would naturally feel that this is muscle spasm related to the hamstrings and gluteus muscles, but on experimenting by injecting procaine hydrochloride I have become more puzzled as to the exact mechanics.

DR. JOSEPH A. FREIBERG, Cincinnati: In this paper I made practically no mention of the piriformis operative procedure, which was first described by Dr. Albert Freiberg, of Cincinnati. The reason for this is that I have felt on further observation that the majority of the sciaticas which are dependent primarily on spasm of the piriformis muscle respond to conservative therapy. I have probably done fewer piriformis myotomies than many of the larger clinics. Regarding the diminution or absence of ankle jerk in many of these low back cases, it is my opinion that all of them cannot be explained. It is a sign of a lower motor neuron lesion, and certainly all orthopedic surgeons have seen many diminished or absent ankle jerks return to normal following conservative therapy. Whether this means, as the neurosurgeons will usually say, that a herniated or protruded disk fragment has returned to its former place of residence, I do not know, but I believe that some of them may be accounted for on the basis of a severe piriformis spasm which has responded to conservative treatment.

THE INCIDENCE OF HEMORRHAGE
OCCURRING WITH PERFORA-
TION IN PEPTIC ULCER

WILLIAM L. WINTERS, M.D.

AND

SHERMAN EGAN, M.D.

CHICAGO

The impression that bleeding ulcers do not perforate and ulcer perforations do not bleed seems to be generally accepted by physicians and surgeons as true. That occurrence of bleeding and perforation together is uncommonly encountered is inferred from references stating that it is well known that bleeding ulcers rarely perforate and vice versa¹ or that bleeding and perforation rarely occur together.² Finsterer,³ in a vast experience, reported finding hemorrhage and perforation occurring together only three times. Blackford and his associates⁴ concluded "bleeding ulcers don't perforate; and ulcer perforations don't bleed." James and Matheson,⁵ however, reported hemorrhage in the presence of perforation of a peptic ulcer and, again, hemorrhage which followed surgical resection of a peptic ulcer. They questioned the validity of the accepted impression.

Bleeding that occurs with peptic ulcer may be described as massive, moderate or slight. The massive hemorrhage is usually sudden in onset and produces the clinical picture of shock, faintness, weakness, rapid pulse, pallor and signs of collapse. Loss of consciousness may occur. Vomiting often follows if the stomach is sufficiently distended or if obstruction to the outlet is present. The vomitus may be described as "blood," "bloody vomitus," "coffee-ground vomitus" or "vomitus stained with blood." The patient is usually able to describe the quantity and consistency. If, however, there is no vomiting, the blood lost is passed as melena. The observing patient will note the black or tarry consistency of the stool, but the unobserving patient may describe the attack he experienced as a fainting spell and allow it to pass as such. Moderate amounts of bleeding more frequently will pass unnoticed. The symptoms of the patient will then be chiefly those of anemia. Pallor may be noted. Exercising may cause palpitation, rapid pulse or dyspnea, or the patient may feel more easily fatigued than formerly. Weakness may be the chief complaint. The character of the stools will be most important, however, and usually gives the clue. Slight amounts of bleeding are usually not detected and are discovered only by a careful history, physical examination or laboratory tests.

Early peptic ulcers that are produced experimentally are covered with a thin gray homogeneous membrane.⁶

Removal of this membrane at the site of the beginning ulcer by a gentle sponging causes profuse bleeding. After the process has eroded the mucosa, it may proceed until the entire wall of the intestine is perforated. The time necessary for an ulcer to develop may be short. The mucosa may be penetrated in a few hours or more. Perforation may occur in a relatively short time after the mucosa has been penetrated. An ulcer may present the typical appearance of a chronic ulcer after three weeks, and an ulcer that is 5 months old may have the gross appearance of an ulcer 1 month old.

It is conceivable, therefore, that in a patient with a peptic ulcer the lesion may become active and cause further ulceration and perforation. This may occur with the patient who gives a brief history of symptoms but has had no management instituted. It may occur with a patient who has had an ulcer for some time, has had it controlled and has been placed under ambulatory management, or it may occur in a patient who has been resistant to management and treatment but has reached the stage where the healing processes are slowly progressive. The ulcerating process may proceed to bleeding by digestion of a thrombus from a previously thrombosed vessel or by erosion of blood vessels that may lie in the deeper structures of the ulcer crater. The amount of bleeding that follows will depend on the size and character of the blood vessel that is eroded, followed by the rapidity of the patient's reparative processes. Perforation, if it should occur, demands no delay in treatment.

In a partial review of the literature to note the incidence of hemorrhage in perforated peptic ulcer, Eliason and Ebeling⁷ collected 240 cases from the literature and found a history of previous hemorrhage twenty-four times. They added to this frank hematemesis in the past history in nine of fifty-four cases and melena in nine of fifty-one cases. Hematemesis at the time of actual perforation was observed four times. Shawan⁸ reported 227 cases, in seventeen of which there was a history of bloody vomitus, and blood was recorded in the examination of the stool eleven times. Rhodes and Collins⁹ reviewed 155 cases, in two of which there was a history of coffee-ground vomitus, but in no case was hematemesis or melena recorded. McCreery¹⁰ reported 170 cases, in five of which there was hematemesis and in thirteen tarry stools. Mondor and Lauret¹¹ noted hematemesis once in seventy-five cases of perforated gastric ulcer. In seventy-five cases of perforated duodenal ulcer abundant hematemesis was reported in two cases and blood-tinged vomitus in two cases.

Raven¹² reported melena twice and hematemesis once in a series of eighty cases. White and Patterson, quoted by Brenner,¹³ reported bleeding in 3 per cent of sixty-two cases. Jirásek and Persky¹⁴ noted fresh blood or coffee-ground material in the vomitus of seven patients in a series of eighty. James and Matheson⁶ stated that they had seen bleeding and perfora-

tion twice in seventy-five cases. Deaver and Pfeiffer¹⁵ noted hematemesis and melena twice in fifty-five cases. Hematemesis at the time of actual perforation was observed four times. Mitchell¹⁶ encountered hemorrhage three times in a series of fifty cases. Brenner¹³ reported a history of melena four times with no hematemesis and melena in a series of fifteen cases.

Blackford and Baker¹⁷ noted massive hemorrhage at the time of perforation in one instance in twenty-one cases. They also stated that slight hematemesis is common. Shawan and Vale¹⁸ reported one case with hematemesis and melena in a series of ten cases. Horsley¹⁹ noted no mention of recent bleeding in eight cases, and in only one of these was there any bleeding at all—hematemesis nine months before. Morrison²⁰ reviewed 200 cases and recorded no bleeding.

from incipience of his ulcer syndrome to its termination and the sequence of events that intervene.

With these thoughts in mind, we reviewed the records of patients with a diagnosis of perforated peptic ulcer who were admitted to Cook County Hospital for the period 1935-1938 inclusive to note the incidence of hemorrhage. Some of these patients had been treated in the various charitable clinics of Chicago prior to the time of their perforation. Many had been patients in the Cook County Hospital at some previous time and, at the time the accident happened, were being treated in the outpatient clinic maintained by the hospital. Other patients had not previously been attended by any physician.

Only patients with histories of peptic ulcer as the essential lesion were selected. Those with a history of some other disease as the essential diagnosis, e. g. arteriosclerosis, cardiac disease, cerebral disease and hepatic disease, with peptic ulcer as the incidental lesion, were not considered.

The diagnosis was made by the usual accepted history and physical evidence of a perforated ulcer. The operative report of repair of a peptic ulcer or report of a perigastric abscess²¹ confirmed the diagnosis in the majority of cases; the fluoroscopic demonstration of air under the diaphragm confirmed the diagnosis in a few cases. An autopsy was made when permission could be obtained.

In reviewing the histories an attempt was made to get a history of ulcer activity, bleeding and perforation that would be clinically significant. Bleeding was not necessarily the most important aspect of the case or even a grave complication, but it was of such amount that it was considered important to the welfare of the patient. A story of hematemesis and melena described as noted previously was considered evidence of bleeding. In many cases study of the stomach contents and stool by direct examination or by chemical tests confirmed the information obtained from the patient. When the history could be traced to what was considered unmistakable evidence of continued ulcer activity (as in the instance of a patient who, while under management, continued to bleed for thirty days with perforation during this period or of a patient who gave a history of hematemesis and melena at varying intervals for one year before entrance and who on entrance had a red blood count of 1,780,000 with perforation) we considered the patient in the group who had perforation with bleeding.

Twenty-two patients were grouped as doubtful. In their histories were such statements as "brown vomitus," "blood-streaked vomitus," "dark stools," "an occasional hematemesis" or "an occasional tarry stool." Several gave a history of bleeding, hematemesis or melena one month or more before their admission. These patients were grouped with those who had non-bleeding perforated ulcers.

The question of hemorrhage was further studied. The amount of bleeding that occurs with an ulcer varies. Patients who bleed severely enough to produce faintness, syncope, rapid pulse, weakness, pallor and signs of shock are usually sufficiently alarmed to be seen by a physician immediately. The amount of hematemesis is estimated by the patient and all too frequently greatly exaggerated. The question of melena is different. The quantity of blood can in no wise be estimated, for the patient can only say that the stool was black

Age incidence of perforated peptic ulcer

The percentage of hemorrhage varies from 1.5 to 18 in the cases reviewed, with an average of 8. From the reviews the relation of the peptic ulcer history of the patient to the hemorrhage, whether by hematemesis or melena, is not evident. Further, the relation of the hemorrhage and ulcer to perforation cannot be elicited. Whether or not one is to defend the statement "bleeding ulcers do not perforate and ulcer perforations do not bleed" depends greatly on what history can be obtained from the patient relative to ulcer activity, hemorrhage and perforation. A significant history should give the connected story of the patient

or of a tarry consistency. Many state that they have suffered no ill effect from such hemorrhage or, at most, only weakness. A question arose as to how much bleeding is necessary to produce a tarry stool but there were no available data to answer it.

A volunteer went on a control diet of milk and cream for twenty-one days and took measured quantities of whole human blood at three day intervals. On such a regimen it was found that 10 cc. of blood caused no noticeable change in the color of the stool. From 20 to 30 cc. turned the stool a brown color which was easily differentiated from the light color of the stool with a milk and cream diet but which could have passed for a normal variation of color from that with a general diet. From 40 to 50 cc. turned the stool progressively darker, so that it would have appeared abnormal even when compared with the variation of a normal diet. However, 60 cc. was required to turn the stool indisputably tarry in color and consistency. With a general unrestricted diet the results were substantially the same, that is, 30 cc. passed as producing a normal variation in color and 40 and 50 cc. as giving a color distinctly darker than normal, but 60 cc. was required to turn it tarry black. It would seem, therefore, that the very minimum amount of blood a patient loses when he has a tarry stool would be between 50 and 60 cc. Clinically this figure probably varies con-

TABLE 1.—Sex Incidence in 361 Cases of Perforated Peptic Ulcer from 1935 to 1938 Inclusive

siderably, for experimentally the blood was all taken at one time and only a relatively small amount of the stool turned black. Further studies on the question are being conducted and will be reported at a later date.

During the years 1935-1938 inclusive 361 patients were admitted to the Cook County Hospital with a diagnosis of perforated peptic ulcer. Of these thirty-six gave histories of bleeding and perforation. Figures for the total number of patients with peptic ulcers admitted for this period are not available. However, for the years 1937-1938, 1,352 patients were admitted with a diagnosis of peptic ulcer, 189 of whom had a perforated peptic ulcer, approximately 50 per cent of the total series for the four year period.

A summary of the differences with respect to age, sex, incidence of perforation and hemorrhage, duration of symptoms and position of the ulcer has been made.

The predominance of the male sex is marked. The ratio agrees generally with statistics from other large charitable clinics.²² However, this is in contrast to the statistics of Hale and White²³ and others quoted by Graves,²⁴ who found that perforation was twice as common in women as in men. In a recent review of autopsy records at Cook County Hospital, Portis and Jaffé²⁵ found the ratio of essential peptic ulcer lesions in male and female patients to be approximately 8:1,

respectively. Hurst and Stewart²³ found a ratio of approximately 2:1. The incidence of peptic ulcer appears to be increasing in males.

The age incidence of perforation and bleeding is of interest. The greatest number of perforations occurred in the fourth decade, although the figures for the third, fourth and fifth decades approximate one another

closely. Following this peak there is a sharp decline to the base line. Bleeding with perforation reached its highest incidence in the sixth decade, approximately twenty years after the incidence of the greatest number of perforations. Arteriosclerosis, either general or localized, is the most probable cause for this variation.

A total of 152 perforated ulcers were found in the stomach. Of these 136 occurred as perforation with no bleeding. Sixty-one were located on the anterior surface of the pylorus and prepylorus, twenty-eight on the lesser curvature of the stomach and four on the posterior wall of the pylorus. Forty-three ulcers were listed as unclassified because the description of the location was ambiguous. While it was felt that the lesion was located on the anterior surface of the pylorus and prepylorus most often, it was not definitely so stated. Sixteen occurred with perforation and bleeding. Nine were situated on the anterior surface of the pylorus and prepylorous, three on the lesser curvature of the stomach and, again, four were unclassified.

* "Unclassified" included terms such as "duodenal ulcer" "peptic ulcer" and "gastric ulcer" without specific description as to its location; that is, the description was equivocal.

A total of 188 perforated ulcers were found in the duodenum, 172 of which occurred as perforation without bleeding. The anterior surface was perforated 105 times, the posterior wall seven times and the second portion twice. Again, fifty-eight were listed as unclassified. Sixteen ulcers perforated and bled. Eight of these occurred on the anterior surface of the duodenum and one on the second portion, and seven were unclassified.

Twelve patients were treated medically, ten for perforation without bleeding and two for perforation and bleeding. Five patients were recorded as having peptic ulcers, four with perforation and no bleeding and one with perforation and bleeding. Four patients were found to have a perigastric abscess, one of whom bled.

There were more ulcers located on the anterior surface of the stomach (nine) and duodenum (eight) that perforated and bled than elsewhere. The ratio of perforation to perforation and bleeding appears to be approximately the same for the ulcers that are located on the anterior wall and for those on the lesser curvature of the stomach. However, one should not lose sight of the fact that many more ulcers are located on the lesser curvature than on the anterior surface of the stomach. This ratio, then, has little significance.

There are certain anatomic peculiarities about the anterior wall of the pylorus and the first portion of the duodenum, where the great majority of perforating ulcers occur. The areas immediately proximal and distal to the pylorus possess a deficient circulation.²⁶ The arteries of the submucosa in the pyloric region of the inferior portion of the lesser curvature are practically terminal vessels and are sparsely distributed, thus giving a limited blood supply to this area.²⁷ These arteries are tortuous, anastomose infrequently and are

to be of value at present. The deficiency in blood supply perhaps explains the frequency of perforation on the anterior surface of the stomach and duodenum. Hemorrhage occurred in approximately 13 per cent of the perforations of the stomach and 8 per cent of the perforations of the duodenum. This may be explained when the relative variation that may occur in the blood supply to these areas is known.

PATHOLOGIC CONSIDERATIONS

Thirteen patients who had perforation without bleeding came to autopsy. Eight had a single ulcer on the anterior surface of the first part of the duodenum. Two had single ulcers on the lesser curvature of the stomach. One patient had three ulcers, of which two were on the anterior surface of the stomach and the third was on the posterior surface of the duodenum. One patient had two ulcers of the stomach, one on the anterior surface and the other on the lesser curvature. The last patient had two ulcers of the duodenum, of which one was on the anterior wall and the other on the posterior wall. Thus three patients had multiple ulcers.

Eight patients who had perforation with bleeding came to autopsy. Seven of these had multiple ulcers; the eighth had a single ulcer on the lesser curvature of the stomach. Of the seven patients who had multiple lesions, one had five ulcers of the stomach, two had ulcers of the stomach and duodenum coexisting and another had multiple erosions of the esophagus and a duodenal ulcer. Three patients had two ulcers of the duodenum; in each case one ulcer was located on the anterior wall and the other on the posterior wall. In two of the latter cases the perforation occurred in the anterior ulcer and hemorrhage from the posterior. The source of bleeding in the remainder was not determined.

The possibility of two or more ulcers must be borne in mind. Gastric ulcers situated on one surface of the stomach may be complicated by an ulcer on another surface of the stomach or by ulcerations elsewhere in the esophagus or bowel. Duodenal ulcers seldom occur with gastric ulcers. Perforation of an ulcer on the anterior surface of the duodenum or stomach has been followed by fatal hemorrhage from an ulcer on the posterior surface of the duodenum or stomach.³⁰ Multiple ulcers have been reported as varying from 18 to 30 per cent in series of perforated ulcers.³¹

The records of nine patients with multiple ulcers were critically reviewed for notes indicating the nature of the pathologic condition that existed prior to autopsy. For two patients surgical repair of the perforation was made. The pathologic picture of one patient was adequately described at operation and no further comment on the gross pathologic changes was made at autopsy. With regard to the other patient, a perforated ulcer located on the anterior surface of the viscus was adequately described but an ulcer located posteriorly was not mentioned.

The remaining seven patients entered the hospital in a serious condition. It was suspected that four had an ulcer perforation, but the condition of each was such that surgical treatment would have been only an added burden to their grave illness. The condition of three patients was undiagnosed. Multiple ulcers in the latter

subject to powerful and repeated constrictions by the musculature of the stomach. Reeves²⁸ stated that he considered the lesser curvature as spreading out to include practically the entire pylorus. He found that because of their anatomic arrangement the arteries along the lesser curvature of the stomach and the first inch of the duodenum are predisposed to thrombosis. The branches from the arterial plexus along the lesser curvature run a highly tortuous course to enter the mucosa; therefore the resistance offered the blood stream is constantly greater and, as a result, the blood current as it enters the smaller arteries of the mucosa is slower.

The rather limited blood supply, the tortuosity of the vessels and the resistance offered the blood stream by the constrictions of the musculature predispose to thrombosis.

Wilkie²⁸ has called attention to the variability of the origin of the blood vessels supplying the duodenum. No other data could be found relative to the variation that may occur in the course of the coronary arteries or major branches thereof of the stomach and duodenum. Anson²⁹ is now conducting research on this question, but the work has not progressed far enough

were not mentioned, although the bleeding from the gastrointestinal tract was a prominent part of the clinical picture.

Microscopic sections were examined in several instances. In each the chronic type of ulcer with sclerous connective tissue base was found. The muscularis was replaced by scar tissue. Round cell infiltration was noted in each section, and eosinophils were infrequent. The base was avascular, and the vessels that were situated here had thick sclerotic walls. The arteries in the neighboring submucosa, muscularis and

that when perforation occurs in the latter it is due to an unusually active process. Behrend³⁴ suggested that perforation occurs in the chronic type of ulcer with a firm sclerotic base and that hemorrhage occurs in the acute type with soft congested edges.

Fifty-one patients (table 4), or 14 per cent, gave no history of symptoms or signs of peptic ulcer prior to their admission for perforation. This is in accord with other reviews.³⁵ Further, there is little variation in the ratio of perforation with the period of symptom activity.

TABLE 5.—History, Hemorrhage and Perforation of Ulcers*

Age, Years	Sex	Duration of History	Duration of Bleeding	Hematemesis and Melena	Location of Perforation and Postmortem Observations
23	♂	4 years	1 day	Tarry stools	Duodenal ulcer
32	♂	Unrecorded	1 day	Hematemesis on admission	Anterior wall pyloroduodenal junction

				Recurring coffee-ground vomitus and tarry stools 1 year; red cell count 1,760,000	

* Fourteen patients (aged from 26 to 72) had a history of hemorrhage from one to six days before perforation. Nine patients (aged from 35 to 65) had a history of from seven to fourteen days' duration. Thirteen patients (aged from 27 to 73) had a history of fifteen days' duration or more.

subserosa had thickened walls. The endothelial lining often showed proliferation, and in at least two instances fairly large arteries were thrombosed. In some cases young granulation tissue was found near the edge of the ulcer. There was a gradual histologic change from the normal tissue surrounding the ulcer process to the sclerotic alterations found in the base of the ulcer. No sections indicative of an acute process were noted. This study would support those who believe perforation occurs more often in the chronic type of ulcer than in the acute.³² Dible³³ stated that bleeding is more common in the acute type than in the chronic type and

Examining the thirty-six patients with hemorrhage and perforation (table 5), it will be noted that fourteen patients had bleeding from one to six days prior to perforation. The majority of patients manifested this by the character of the stools. A few noted hematemesis. In one patient multiple erosions of the esophagus, as well as an ulcer of the duodenum, were found at autopsy. The condition of this patient at the time of entrance to the hospital was such that surgical intervention was contraindicated. The origin of the bleeding may be questioned. It may have originated from the esophageal erosions. However, from the data

reviewed, the duodenal ulcer played an important part in the production of the symptom complex. Neither the age of the patient nor the duration of the ulcer history made any difference in the tendency to hemorrhage and perforation. It occurred in all decades after the second. Nine patients noted hemorrhage from seven to fourteen days before perforation. Again, the tendency to bleeding perforation occurred with the same abandon as noted in the earlier group. Thirteen patients noted bleeding fifteen days or more prior to perforation. It is in this group that the history of intermittent or recurrent bleeding is noted. One patient who was bleeding was thought to be immune to perforation because "bleeding ulcers do not perforate." Also the multiple ulcers are found more frequently. The repeated loss of blood seems to play a part in lowering the resistance of the patient to the factors responsible for ulceration of the bowel. Sufficient bleeding to produce tarry or black stools was noted in the majority of patients prior to symptoms indicating perforation. The amount of blood lost can in no wise be determined. It would seem, then, that a patient with a known ulcer history who suddenly manifests signs of hemorrhage should be looked on as a candidate for a more serious and grave complication of ulcer—perforation.

Statistics on the incidence of hemorrhage in peptic ulcer vary considerably and for this reason are difficult to evaluate. When one adds to them the statistics on the incidence of perforation, the task becomes increasingly difficult. The total number of ulcer patients for the four year period 1935-1938 inclusive are not available. However, during this period 361 patients who had peptic ulcers with perforation were admitted, and thirty-six of them, approximately 10 per cent, had a history of bleeding preceding the perforation. For two years of the period (1937 and 1938) 1,352 patients with peptic ulcer were admitted, and of these 189 had perforation. Applying the percentages to the latter group, one finds that approximately 1 per cent of the patients with peptic ulcer bled and perforated. While this group may be too few in number for one to draw any conclusions, it might be better to say that bleeding and perforation occur in approximately 1 per cent of peptic ulcers than to say "bleeding ulcers don't perforate and ulcer perforations don't bleed."

SUMMARY AND CONCLUSIONS

Three hundred and sixty-one patients with perforated peptic ulcer that entered Cook County Hospital during the years 1935-1938 inclusive were reviewed to note the incidence of hemorrhage. Bleeding and perforation in a peptic ulcer do occur together. For the four years reviewed, bleeding was present in 10 per cent of the patients with perforated ulcer, and bleeding and perforation occurred in approximately 1 per cent of all patients admitted with the diagnosis of peptic ulcer during the years 1937 and 1938. Approximately 60 cc. or more of blood has escaped into the bowel when a patient has melena. Perforation in peptic ulcers occurred more often in males than in females. It occurred most frequently in the fourth decade, although the fifth decade showed almost the same number of cases. Bleeding and perforation occurred most frequently together in the sixth decade. Hemorrhage that follows surgical repair of a perforation should arouse suspicion that an ulcer situated elsewhere in the gastrointestinal tract may be responsible for the bleeding.

PRIMARY TUBERCULOUS INFECTION ATTACK RATES

OBSERVATIONS FOR SELECTED LOCAL POPULATION GROUPS

C. A. STEWART, M.D.; F. E. HARRINGTON, M.D.

J. A. MYERS, M.D.; R. E. BOYNTON, M.D.

P. T. Y. CHIU

AND

T. L. STREUKENS

MINNEAPOLIS

The observations reported in this paper were made recently on a total of 3,868 persons representing five different groups included in the population of Minneapolis and St. Paul (summarized in the accompanying table). The data obtained reveal the existence of wide variations in the current rates at which different groups are acquiring infections with tubercle bacilli. Analysis of these observations is undertaken for the purpose of demonstrating which of the surveyed groups experienced an exceptionally high infection rate which can be greatly reduced. The general significance of our observations presumably is proportional to the degree to which the records for each group studied are representative of the experience in comparable groups residing elsewhere.

During the course of an epidemiologic survey conducted in private practice on the personnel of a series of household units,¹ 0.1 mg. of old tuberculin was administered intradermally to 1,278 children and to 1,192 of their respective parents.

When tested at an average age of 6.4 years, 5.2 per cent of the children proved to be sensitive to tuberculo-protein. From these records it is evident that infection with tubercle bacilli had been acquired by about 0.8 per cent of the group annually. This relatively low crude annual contamination rate is used here as a standard with which the annual infection rates observed for other groups whose records appear in the table are compared. In order to facilitate these comparisons, an arbitrary value of 1 is assigned to the crude annual primary tuberculous infection attack rate² recorded for the 1,278 children surveyed in private practice.

The data for the 1,192 parents included in this study show that 57.6 per cent were sensitive to 0.1 mg. of the old tuberculin when tested at an average age of 36.3 years. According to these observations, this group of adults had acquired infection with tubercle bacilli at a crude average rate of about 1.6 per cent annually. Since the annual primary infection attack rate recorded for these parents is double the average contamination rate observed for their children, the latter apparently have been exposed to roughly one half the mean effective infection risk that the former faced. Whether these observations reflect the general trend during the past three decades in the tuberculous infection risk prevalent in Minneapolis homes of the type represented in this study or reveal a current difference in the frequency with which children and their respective parents are now being exposed to open cases of tuberculosis is an interesting and speculative question. Observations published recently by Harrington, Myers and Levine³

provide evidence to the effect that the rate at which Minneapolis children are infected with tubercle bacilli declined appreciably during a period of ten years.

Data collected by Myers, Diehl and their associates,⁴ for 173 students who gave negative Mantoux reactions when they entered the college of education at the University of Minnesota show that 5.8 per cent became sensitive to tuberculin during their four year course of study. The average annual rate at which infections with tubercle bacilli were introduced into this series of young adults (1.5 per cent), like that (1.6 per cent) recorded for the parents included in this study, is practically double the crude primary tuberculous infection rate of 0.8 per cent obtained for the children whose records appear in the table. Although the environment of these children seems to have been safer on the average than that of students enrolled during the same decade in the college of education at the University of Minneapolis, nevertheless the tuberculous infection risk to which the latter were exposed recently probably can be rated as being comparatively low but susceptible probably to improvement.

A follow-up study conducted on 289 medical students who failed to react positively to 0.1 mg. of old tuberculin

of study and is fifty-six times the infection attack rate recorded in the table for Minneapolis children who were residing in private homes. Obviously an exceptionally high contamination risk was experienced by these medical students during their clinical or senior year.

Data have also been collected for a group of 276 student nurses who failed to react positively to 0.1 mg. of old tuberculin at the time they started a three year course of study in local private hospitals that maintain no beds for tuberculous patients. Of this group of 276 originally uncontaminated young adult girls, eighty-four, or 30.4 per cent, were found to be sensitive to 0.1 mg. of tuberculoprotein at the time of graduation. Roughly 10.1 per cent of the group had acquired infections with tubercle bacilli each year. This annual tuberculous infection rate is approximately twelve times that observed for the Minneapolis children whose records appear in the table. This observation is interpreted as evidence that a relatively high risk of acquiring infection with tubercle bacilli confronts nurses during their period of training in hospitals that maintain no special tuberculosis service. Apparently unrecognized human dissemination of tubercle bacilli are inadvertently

Crude Annual Primary Tuberculous Infection Attack Rates for Different Local Population Groups

Source of Data	Environment During Period of Observation	Total Number	Time Spent in Environment, Years	Number and per Cent Infected During Time Spent in Environment		Average Annual Increase in Infections (per Cent): "The Crude Annual Primary Infection Attack Rate"	Ratio of Each Infection Attack Rate to That Found for Minneapolis Children	Estimated Time Required for 100 per Cent of Each Group to Be Infected, Years

* Tuberculin reaction negative to 0.1 mg. of tuberculin when study was commenced.
† Tuberculin reaction negative to 1 mg. of tuberculin when study was commenced.

at the time they entered the college of medicine of the University of Minnesota disclosed that twenty-four, or 8.3 per cent, had become sensitive to this dose of tuberculoprotein by the time they had finished their junior year in school. During this three year period of study, which provided very little contact with patients and included no special tuberculosis service, 2.8 per cent of the group was infected each year. This crude annual primary tuberculous infection rate is three times that observed for the children whose records are used here as a basis for comparison.

According to the records of the Student Health Service at the University of Minnesota, 265 of the original group of 289 uninfected students continued to show negative reactions to 0.1 mg. of old tuberculin applied at the beginning of the senior year. During the last or clinical year of their course, the 265 young adults who started their senior year uncontaminated not only devoted much of their time to examining and treating patients but also spent two weeks on a special tuberculosis service. At the end of the senior year 118 members of the group were found to be sensitive to tuberculoprotein. The annual tuberculous infection rate observed for this group of medical students amounts to 44.5 per cent, which is sixteen times the annual rate noted for each of the first three years of their course

admitted to institutions of this character with appreciable frequency. If these local records provide an approximate estimate of what is taking place in private hospitals throughout the country, it seems quite obvious that an important preventable but generally unappreciated health hazard exists in institutions that knowingly admit few or no tuberculous patients for treatment. The correction of this situation probably is contingent not on refusing to admit tuberculous patients to private hospitals but rather on adopting the general policy of practicing strict aseptic nursing technic in connection with the care and treatment of each patient admitted to a private hospital until Mantoux tests applied as a routine and subsequent roentgenologic, laboratory and clinical examinations of each infected tuberculin-sensitive patient demonstrate the absence of a readily communicable form of tuberculosis, particularly open chronic pulmonary tuberculosis or phthisis.

The tuberculous infection rate recorded for the nurses training in hospitals which maintain no special tuberculosis service was distinctly lower than that observed for other student nurses whose course included a period during which tuberculous patients were given care. The records for 344 student nurses who entered training with negative reactions to 0.1 mg. of old tuberculin and spent three years in hospitals which provided six weeks training in special tuberculosis wards show that 204, or 59.3 per cent, of the group had acquired infection

4. Myers, J. A.; Diehl, H. S.; Lees, H. D., and Levine, I.: Tr. Nat. Tuberc. A., thirtieth annual meeting, Cincinnati, 1934, p. 345.

with tubercle bacilli during their three year course of study. The crude annual primary tuberculous infection rate observed for these students amounts to 19.8 per cent, which is nearly twice that recorded for nurses whose course of study provided no training in wards for tuberculous patients and is twenty-five times the rate recently experienced by Minneapolis children residing in private homes.

A follow-up study on an additional group of 158 student nurses who entered training with negative reactions to 0.1 mg. of old tuberculin and spent three years in hospitals whose course of study included three months' service in wards for tuberculosis patients disclosed that 141, or 89.2 per cent, of the group acquired infection with tubercle bacilli during a period of three years. The crude annual contamination rate observed for this group of young women is nearly three times the infection rate observed for nurses whose course included no special tuberculosis service and is thirty-seven times that recorded in the table for Minneapolis children. Attention is also called to the fact that the increases in infections recorded for the two groups of nurses who worked in wards for tuberculous patients were roughly proportional to the length of time each group spent in this type of service.

The high tuberculous infection attack rates recorded here for Minneapolis nurses whose course included a tuberculosis service are comparable to those reported by Geer⁶ for groups of nurses also engaged in caring for tuberculous patients in hospitals in St. Paul. According to the data given in the accompanying table in Geer's communications, 75.9 per cent of 158 who entered training with negative reactions to tuberculin acquired infection with tubercle bacilli during an average period of about 1.1 years. For this group of nurses the annual primary infection attack rate (69 per cent) is approximately eighty-six times the rate observed for the Minneapolis children included in this study.

Although the data that have been considered up to this point show that infections are acquired at exceptionally high rates by those engaged in the care of tuberculous patients, nevertheless these observations are open to the objection that 0.1 mg. rather than 1 mg. of old tuberculin was used as a routine in determining whether infection with tubercle bacilli was absent or present. Fortunately, however, Dr. Ruth Boynton, director of the Student Health Service at the University of Minnesota, was able to provide observations on a group of 170 nurses who gave negative reactions to 1 mg. of old tuberculin immediately before they undertook a tuberculosis service of six weeks' duration. One hundred and fifty-eight of these nurses were retested four weeks after the special tuberculosis service was terminated; thus data are available which accurately reveal the true rate at which primary infections were acquired by the group during this brief period of contact with tuberculous patients. According to the data in the table, thirty-five, or 22.2 per cent, had made the transition from the uninfected to the infected state in a period of ten weeks. These nurses, therefore, experienced a primary tuberculous infection rate, which, computed on an annual basis, amounts to 115.4 per cent. This infection rate is 144 times the infection rate observed for the children whose records are used here as a basis for comparison. Since all these contaminations probably were acquired during the six weeks spent with tuberculous patients, it seems reason-

able to attribute the 22.2 per cent increase in infections observed for these nurses to this short period of special training. When computed on this basis, the corrected annual primary tuberculous infection attack rate attributable to six weeks' contact with tuberculous patients amounts to 192 per cent, which is 240 times the contamination rate recorded in the table for Minneapolis children. The careful observations made on this group of 158 student nurses and the mutually confirmatory data for other groups whose records are included in this report are interpreted as conclusive evidence that infections with tubercle bacilli are acquired at exceptionally high rates by those who are engaged in the care of tuberculous patients. These observations also demonstrate that institutions maintained not only for the care of tuberculous patients but also for the purpose of protecting the public from contact infections by segregating disseminators of tubercle bacilli can serve as prolific centers of contagion where a large number of new human cultures of tubercle bacilli are produced annually if previously uncontaminated attendants are not given the protection of rigid aseptic measures. The serious consequences of infections acquired by students of nursing and medicine during their period of training has been reported recently by Myers and his associates.⁶

When follow-up studies disclosed the importance of the relatively unobtrusive health menace which confronts students registered in the college of medicine and nursing at the University of Minnesota, the faculty adopted measures designed to reduce this hazard to a minimum. These measures include the routine application of Mantoux tests to the professional and nonprofessional staffs of the hospital and periodic clinical and roentgenologic examinations of each tuberculin sensitive individual discovered in this manner. In addition, there was instituted the policy of observing aseptic technic in connection with the care of new hospital admissions until Mantoux tests and subsequent examinations of tuberculin sensitive patients excluded the presence of communicable forms of tuberculosis. Furthermore, a special tuberculosis service has been established by Dr. F. E. Harrington at the Minneapolis General Hospital, where attempts are being made to perfect a technic which will prevent attendants from acquiring infections with tubercle bacilli while working with tuberculous patients. The results of tuberculin tests periodically reapplied to previously uninfected persons during and after a period spent with tuberculous patients are expected to serve as an index of the efficiency of the prophylactic measures that are now being practiced. This follow-up study probably will reveal what is required to prevent those caring for patients with open cases of tuberculosis from being contaminated. The experience reported by Geer indicates that only the most rigid aseptic measures will prove adequate.

In order to obtain special information relative not only to the experience with tuberculous infection of students in other universities but also concerning precautions exercised elsewhere to keep this hazard at a minimum, a letter of inquiry was addressed to the deans of the medical schools of the United States and Canada. Replies to this communication received from forty-nine schools revealed that the problem is receiving very careful attention in some places but is largely neglected in other institutions. According to the reports

BURN SHOCK—TRUSLER ET AL.

2207

received from several universities, the high rate at which their respective students of nursing and medicine are acquiring infection with tubercle bacilli is a question of deep concern to the faculty, and definite efforts are being made to correct the situation.

Reports submitted by a few universities in which the question of tuberculosis in students of medicine and nursing has been investigated indicate that this special health problem seems to be distinctly less important in some institutions than in others, and in some instances the local tuberculous infection risk was rated as inconsequential.

A general consideration of all the information supplied by the various medical schools of the United States and Canada suggests that the study of the rate at which infections with tubercle bacilli are being acquired by students of medicine and nursing, and the development of methods designed to reduce this menace to a minimum, are in their infancy. Several universities are planning a special investigation of local conditions; thus an increasingly exact concept of the prevalence and magnitude of this special health problem and also of the measures required for its solution may soon be available.

CONCLUSION

The tuberculous infection risk prevalent in private hospitals and particularly in institutions that maintain wards for tuberculous patients constitutes a public health problem of sufficient importance to require careful investigation.

City Hall.

BURN SHOCK

THE QUESTION OF WATER INTOXICATION AS A COMPLICATING FACTOR: BLOOD CHEMICAL STUDIES AND REPORT OF AN EXTENSIVE BURN TREATED BY REPEATED TRANSFUSIONS OF BLOOD AND BLOOD PLASMA

H. M. TRUSLER, M.D.
H. L. EGBERT, M.D.

AND
H. S. WILLIAMS, M.D.
INDIANAPOLIS

It is common knowledge that cases of extensive burn are likely to terminate fatally. Seldom does recovery occur from a burn which involves half the body surface, even though the burn is superficial. There are many who die from burns involving considerably less than half the body surface. This is especially true of children.

Furthermore, it is known that patients with severe burns are liable to a variety of complications such as pneumonia, nephritis, embolism, perforating ulcer of the bowel, sepsis and various other pathologic states, any of which may be contributory causes of death. We mention these only to avoid possible confusion in the discussion which follows. Our principal theme concerns the acutely fatal shock reaction which comes a few hours or a few days after the burn.

The symptoms and course of the burn shock state are variable. Too often death comes unexpectedly in

a case thought to be progressing favorably. With very large burns death comes quickly. The clinical picture is circulatory stasis progressing to a fatal termination.

The pulse becomes weak, and the blood pressure falls. The patient may be comfortable and often euphoric, so that the impending death is difficult to realize. Soon, however, the pulse cannot be palpated, the extremities become cold and livid or pallid with cyanosis, and the blood becomes thick and dark. The patient becomes stuporous and then comatose. Death terminates the picture within a few hours of the burn.

In the burned patient who lives for several days, the shock syndrome is more complicated. There may be pulmonary edema, vomiting, hyperpyrexia, progressive anasarca, convulsions and coma. Circulatory collapse terminates the course.

It is this latter group of symptoms which is usually ascribed to toxemia. The toxic theory has assumed that the burned flesh breaks down into poisonous split proteins which are absorbed into the circulation. It was this conception which led Davidson¹ to the tannic acid treatment with the thought of "fixing" toxins. Fluids were forced, to aid in the elimination. It is now known that this theory is fallacious. Certainly the treatment based on it has not prevented death from burn shock.

MECHANISM OF BURN SHOCK

The chief factor is the reaction of the capillaries to thermal injury.

Subsequent to a burn the capillaries in the injured areas dilate. The circulation stagnates, and blood plasma escapes through these injured capillaries into the tissue spaces. If the burn involves a sufficient number of capillaries the patient dies of shock due to a loss of blood fluid so rapid that nothing can be done to replace it. Intravenous fluids merely wash out into the tissue spaces. This is true circulatory shock from the mechanical loss of fluids, as reported by Blalock.² If the burn is of lesser degree, so that fluid balance can be maintained, the patient survives the immediate shock stage. The inflammatory reaction of the capillaries persists, with continued loss of blood fluid and stagnation of the circulation.

One may observe all the local and general signs of the inflammatory reaction. Locally there are redness, heat and edema. The systemic reaction comprises fever, malaise, vomiting, convulsions and the other "toxic" symptoms previously mentioned. In other words, the toxic manifestations of burns are merely the systemic effects of diffuse thermal inflammation.

The escape of fluid from the capillaries becomes generalized, extending first to the liver, lungs and other parenchymatous organs and finally to all parts of the body. Because of the obvious inspissation of the blood and the fever it is common practice to force fluids intravenously and by mouth. Burned patients are thirsty because of the fluid loss and will drink enormous quantities of water. This is especially true of children, and because of the difficulty of intravenous fluid therapy for these patients they are often encouraged to take large amounts of fluid by mouth, the idea being that fluids of all kinds are indicated and can do no harm under these conditions.

2. Blalock, Alfred: Experimental Shock: VII. The Importance of the Local Loss of Fluid in the Production of the Low Blood Pressure After Burns, Arch. Surg. 22: 610 (April) 1931.

Dr. W. D. Gatch approved this work and assisted in the preparation of the manuscript.
From the Research Division and the Department of Surgery, Indiana University Medical Center.
Treatment demonstrated in space 488 in the Scientific Exhibit at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 15-19, 1939.

It is now known, however, that this reasoning is fallacious. When these patients are encouraged to take large quantities of water by mouth the burn shock is thereby complicated by a waterlogging of blood and tissues and by a metabolic disturbance which, for want of a better term, we have called water intoxication.

WATER INTOXICATION

Before discussing further the relation of water to burn shock it may be well to review briefly the subject of water intoxication as reported under other condi-

Fig. 1 (case 1).—A girl aged 2 years who suffered a hot water scald resting comfortably eighteen hours after treatment by the tannic acid-silver nitrate method of Bettman. On the fourth day she died in convulsions.

tions. The subject was first introduced by Rowntree³ in 1923. He had noticed a peculiar symptom complex in several patients with diabetes insipidus who continued to drink their customary large quantities of water after urinary output had been sharply reduced by solution of posterior pituitary. Rowntree then gave large quantities of distilled water to animals by mouth and observed a syndrome which he called water intoxication, characterized by progressive asthenia, muscular twitchings, convulsions, coma and death. The chief pathologic feature observed to be present was cerebral edema accompanied by a sharp reduction in the serum chlorides.

Because of the fact that enormous amounts of water are necessary to produce alarming symptoms under ordinary conditions, little or no practical importance was attached to Rowntree's observations. Later, however, it was recognized that the so-called heat cramps of engine room and furnace workers are produced by drinking large amounts of water following excessive loss of chloride in perspiration. This condition may be prevented or relieved by proper salt intake. This same mechanism is responsible, in part at least, for the condition known as heat exhaustion.

Interest in the subject of water intoxication was again aroused in 1935, when Helwig, Schutz and Curry⁴ reported a fatal case. In this instance a woman aged 50 died in convulsions thirty hours after a simple cholecystectomy. She had received by proctoclysis 9,000 cc. of water in the thirty hours.

WATER INTOXICATION IN RELATION TO BURN SHOCK

Proceeding from these introductory remarks we are now ready to present the evidence which has given us a new conception of burn shock and the blood chemical disturbances related thereto. The thought that water

intoxication may sometimes complicate burn shock came to us as the result of observations made in the following case:

CASE 1.—A girl aged 2 years was admitted to St. Vincent's Hospital, Indianapolis, on March 6, 1937, within an hour after she had fallen backward into a tub of hot water. The child was taken to the surgery and, under suitable narcosis, she was cleansed and her burns were treated by the tannic acid-silver nitrate method of Bettman.⁵ Two hours after her burn she was completely tanned and comfortable in bed. The thin black membrane constituted what seemed to be an excellent dressing for her burn, as shown in figure 1.

It was apparent that the burns were superficial, but they were so extensive that a grave prognosis was given. The subsequent treatment was that which is prescribed in modern textbooks of surgery: namely, the forcing of fluids, the giving of large quantities of fruit juices, alkalis and calcium by mouth, and the intravenous administration of physiologic solution of sodium chloride and dextrose. The question of blood transfusion was discussed, but no blood was given.

Under this management the patient's condition seemed good for forty-eight hours. She asked for and was encouraged to take large quantities of fluids by mouth. Physiologic solution of sodium chloride and dextrose were given intravenously in moderate amounts. Though her condition seemed good, her burned areas became edematous on the second day.

On the third day the child became stuporous but could be aroused and would take large amounts of water and fruit juice. Rapidly a generalized edema developed, and at the end of seventy-two hours she went into convulsions and remained unconscious until her death six hours later, during which time her generalized edema continued to increase. Blood drawn near the time of death showed profuse hemolysis of red cells, practically no clot formation and a blood chloride reading of 140 mg. per hundred cubic centimeters—a figure so amazingly low that the determination was rechecked.

Necropsy performed promptly after death revealed a tremendous waterlogging of all tissues with quantities of free fluid in the abdomen and chest cavities. The liver was greatly swollen, pale and hard. The heart was firm and contracted; the lungs were moist but showed no consolidation. There were petechial hemorrhages in the mucosa of the pyloric antrum of the stomach and the duodenum. Kidneys and other viscera showed little gross change. The brain was not examined, but it is logical to assume that it was involved in the generalized edema. Smear and cultures of the heart's blood were negative for bacteria. Microscopic examination of tissues revealed edema

Fig. 2 (case 1).—Temperature chart.

and cloudy swelling, most apparent in the liver, which showed extreme parenchymatous damage. There was necrosis of the splenic corpuscles in varying degrees of severity. The kidneys showed cloudy swelling and parenchymatous degeneration. The corium of the superficially burned skin showed edema and capillary engorgement but no other evidence of infection.

This clinical picture obviously presents a far more profound disturbance than the water intoxication syndrome described by Rowntree. For want of a better term, however, we feel justified in assuming that this may be water intoxication superimposed on burn shock.

3. Rowntree, L. G.: Water Intoxication, *Arch. Int. Med.* 32: 157 (Aug.) 1923.

4. Helwig, F. C.; Schutz, C. B., and Curry, D. E.: Water Intoxication, *J. A. M. A.* 104: 1569 (May 4) 1935.

5. Bettman, A. G.: Tannic Acid and Silver Nitrate in Burns, *Surg., Gynec. & Obst.* 62: 458 (Feb., No. 2A) 1936.

In this case, unfortunately, blood chemical studies were incomplete. However, the extremely low terminal blood chloride level and the massive waterlogging of all tissues are positive observations of great significance.

The laking of the red blood cells is evidence of a profound disturbance in osmotic relations. The failure of the blood to clot suggests a decrease in fibrinogen associated with a great dilution of blood proteins. Also, we are inclined to postulate that the convulsions which preceded this baby's death should be ascribed to water intoxication.

EXPERIMENTAL STUDIES

This rather startling hypothesis led us to a series of studies on experimental animals (dogs). The animals were carefully selected for uniformity. They were clipped free of hair to the neck and were washed clean. Blood was drawn for determination of normal values. In order to produce definitely controlled burns, the animals were given morphine and a light ether anesthetic and immersed in water to the shoulders, the degree of burn depending on the temperature of the water and the time of immersion. After this they were kept comfortable and free from pain by adequate narcosis and careful attendance.

These animals were observed in series of five. Each member of a series received a different type of management, as follows:

- (a) No fluids given.
- (b) Water forced by stomach tube.
- (c) Physiologic solution of sodium chloride and dextrose administered intravenously in large amounts.
- (d) Acacia given intravenously in addition to solution of sodium chloride and dextrose.
- (e) Transfusions of blood given twice a day in addition to salt solution and dextrose.

The following observations were made:

1. When the burns were relatively slight all animals tended to survive irrespective of treatment. There is one notable exception to this statement. An animal with a relatively slight burn can be killed by the persistent forcing of water by mouth. When liberal quantities of water are given by stomach tube to the animal with a mild degree of burn shock it is most likely to die in convulsions. The terminal blood picture is that of water intoxication. The control animal which is made comfortable by suitable narcosis takes little or nothing by mouth. It rests and very likely survives the shock state. Moderate amounts of salt and dextrose given intravenously are perhaps beneficial but are not essential to the recovery of animals with moderate degrees of burn shock. As previously stated, they tend to recover spontaneously unless large amounts of water are administered, in which case they die usually in convulsions.

2. When the burns were too severe all animals died in shock, commonly within twelve hours. In this group blood transfusions, given promptly and repeated frequently as the shock state progressed, tended to prolong life for many hours. Salt solution and dextrose given intravenously in the absence of blood transfusions were useless for the severely burned animals. The addition of acacia was of no benefit.

3. When the burns were of critical degree but not utterly hopeless in severity we made observations as follows:

- (a) The control animals, to which no fluids were given, invariably died in shock, ordinarily within twelve hours.

- (b) The animals which received large quantities of water by stomach tube tended to survive longer than the controls but always died, usually in convulsions.

- (c) Salt solution and dextrose given intravenously in large quantities likewise tended to prolong life a few hours, during which time edema of the burned areas increased rapidly. Animals receiving this treatment died in shock regardless of the amount of fluid given.

- (d) The addition of acacia to the intravenous solution was ineffective in saving life.

- (e) The animals which received repeated large transfusions of blood in addition to salt and dextrose given intravenously were able to survive the otherwise fatal shock state. They became edematous but tended to maintain a normal blood chemical balance.

Numerous blood chemical observations were made. A detailed discussion of our experiments would be laborious and fortunately is unnecessary. We are including a few typical protocols which illustrate our observations under the stated conditions.

BLOOD CHEMISTRY⁶

PROTOCOL 1 (a).—Mild burn shock; recovery; no treatment.

No. 364, weight 12.3 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 60 C. for thirty seconds. The animal was given no treatment and survived the burn shock. There were no significant blood chemical changes at the end of fifty hours.

TABLE 1.—Blood Chemistry, Protocol 1(a)

	Normal	After 50 Hours
Hemoglobin, Gm.	14	14.5
Serum proteins, Gm.	7.1	6.8
Serum chlorides, mg.	662	643
Calcium, mg.	10.4	11.5
Sugar, mg.	85	83
Total nonprotein nitrogen, mg.	30	29

PROTOCOL 1 (b).—Mild burn shock. Death in forty-eight hours; water intoxication.

No. 365, weight 13.2 Kg. In this experiment the procedure was the same as protocol 1 (a) except that large amounts of tap water were given by stomach tube. The first convulsion occurred after twenty-four hours. The animal died in coma forty-two hours after the burn, having received 7,000 cc. of tap water.

Note the sharp reduction in blood chlorides and the dilution of serum proteins. This was fatal water intoxication superimposed on the mild burn shock.

TABLE 2.—Blood Chemistry, Protocol 1(b)

	Normal	At Death
Hemoglobin, Gm.	13	9.5
Serum chlorides, mg.	653	394
Serum proteins, Gm.	7.1	4.7
Sugar, mg.	99	56
Total nonprotein nitrogen, mg.	37	32
Calcium, mg.	11.5	9.5
Potassium, mg.	22	23

PROTOCOL 2.—Fatal burn shock.

No. 666, weight 20 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 72 C. for three minutes. It was treated by seven transfusions of 400 cc. of whole blood, each combined with similar amounts of physiologic solution of sodium chloride with dextrose. Enormous edema developed, and death occurred at the end of forty-six hours.

Blood chemical observations at death revealed a sharp increase in hemoglobin and an elevation of total nonprotein nitrogen. It is significant that though large amounts of blood were given there was no increase in total serum protein. In other words it seems that blood plasma was lost into the tissues as rapidly as the blood transfusion replaced it. The change in the albumin-globulin ratio is significant.

6. The blood chemical figures in the tables are expressed as follows: Hemoglobin and serum proteins are determined as grams per hundred cubic centimeters; serum chlorides, serum calcium, blood sugar and total nonprotein nitrogen as milligrams per hundred cubic centimeters, and hematocrit value as per cent volume of the cells in 100 cc. of blood.

TABLE 3.—*Blood Chemistry, Protocol 2*

	Normal	At Death
Red cell count, millions per cu. mm....	7.83	8.40
Hemoglobin, Gm.	15.5	25
Serum chlorides, mg.....	673	663
Serum proteins, Gm.....	6.9	6.9
Albumin, Gm.	4.1	3.5
Globulin, Gm.	2.8	3.4
Sugar, mg.	114	125
Calcium, mg.	10.8	18.3
Total nonprotein nitrogen, mg.....	30	98

PROTOCOL 3 (a).—Critical shock; no treatment; death in eleven hours.

No. 408, weight 18.8 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 72 C. for one minute. No treatment was given. The animal died in shock eleven hours after the burn.

The blood chemical changes here were essentially the same as those observed in the animal described in protocol 2, which died in shock despite transfusion of enormous amounts of blood. There were an increase in hemoglobin and a sharp increase in the hematocrit percentage, indicating an actual loss in blood plasma. The chemical observations on the plasma which remained in the vessels showed little or no change.

TABLE 4.—*Blood Chemistry, Protocol 3 (a)*

	Normal	At Death
Hematocrit, %	45	62

Sugar, mg.	105
Calcium, mg.	11.1	10.1

PROTOCOL 3 (b).—Critical shock; water by stomach tube; death in sixty hours.

No. 376, weight 17.5 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 72 C. for one minute. It was given 7,000 cc. of tap water by stomach tube, much of which was vomited. Death ensued after sixty hours without convulsions.

The most significant blood chemical change noted here was the sharp fall in serum chlorides, the marked reduction of sugar and the terminal increase in nonprotein nitrogen. This is the picture of water intoxication superimposed on a critical state of shock.

TABLE 5.—*Blood Chemistry, Protocol 3 (b)*

	Normal	At Death
Hemoglobin, Gm.	13	13
Serum proteins, Gm.....	7.2	6.5
Serum chlorides, mg.....	672	374
Calcium, mg.	10.5	9.8
Sugar, mg.	128	26
Total nonprotein nitrogen, mg.....	37	167

PROTOCOL 3 (c).—Critical shock; physiologic solution of sodium chloride and dextrose given intravenously in large amounts; death in twenty-four hours.

No. 546, weight 28.6 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 72 C. for one minute. It was treated with 3,000 cc. of physiologic solution of sodium chloride with 5 per cent dextrose. Death ensued in twenty-four hours.

In this instance one notes the fall in the serum protein, reduction of blood sugar and terminal increase in total nonprotein nitrogen (discussed under blood chemical changes).

TABLE 6.—*Blood Chemistry, Protocol 3 (c)*

	Normal	At Death

Total nonprotein nitrogen, mg.....	26	82

PROTOCOL 3 (d).—Critical shock; physiologic solution of sodium chloride and dextrose and 6 per cent acacia given intravenously in large amounts; death in fifty-six hours.

No. 451, weight 15.19 Kg. This animal was given morphine and a light ether anesthetic. It was then immersed to the shoulders in water at 72 C. for one minute. It was given three intravenous injections during the next thirty-two hours, each consisting of 500 cc. of physiologic solution of

sodium chloride containing 6 per cent acacia and 5 per cent dextrose. Death occurred twenty-four hours after the last injection as blood was being drawn for studies on blood chemistry. There were marked prolongation of bleeding and clotting time and hemolysis of the blood.

This experiment revealed the most marked changes in blood chemistry. Note the sharp reduction of hemoglobin, the fall in the hematocrit value, the fall in the serum proteins and the reduction in blood sugar (discussed on blood chemical changes).

PROTOCOL 3 (e).—Critical shock; repeated blood transfusions; recovery.

No. 537, weight 19.5 Kg., given morphine and a light ether anesthetic. It was then immersed in water at 72 C. for one minute. This animal was given repeated transfusions, 300 cc. of whole blood plus 300 cc. of 10 per cent dextrose being administered in physiologic solution of sodium chloride. Three such intravenous injections were given the first day and one each day thereafter. The animal was killed after one week.

This subject survived the burn shock. It should be noted that blood chemical values at the time the animal was killed were essentially normal.

BLOOD CHEMICAL CHANGES

The first point that we wish to emphasize is the variation in the blood picture, which depends on the degree of shock and the manner in which fluids are administered. Unless these factors are taken into account, the blood chemical values of shock have little or no significance. The physical mechanism of the shock state is obviously complicated. There are, however, two morbid phenomena which are definite: (1) circulation is stagnating and (2) blood fluids are escaping from the capillaries. This situation produces progressive degrees of blood concentration.

If no fluids are given, the blood chemical changes noted at death are those of blood concentration, as reported by Osterberg⁷ and by Underhill and others.⁸ When fluids are forced over several days' time, however, the blood chemical picture is different. The continued forcing of fluids by mouth can result in a condition of "water intoxication," which is apparent in the blood chemical picture at death. The continued intravenous administration of salt solution merely adds salt. Neither of these fluids will support life, nor will they stay in the capillaries.

When the shock state progresses rapidly, the change in chemical composition is often so slight that there may be no apparent explanation for the death of the animal. Note protocol 3 (c); critical shock terminated fatally in twenty-four hours, during which time 3,000 cc. of saline solution and dextrose was given to an animal weighing 28 Kg. The chemical changes as shown in the table seem insignificant at first thought. However there was

7. Osterberg, A. E.: Symposium on Acute Burns: Biochemical Studies, Proc. Staff Meet., Mayo Clin. 8: 121 (Feb. 22) 1933.

8. Underhill, F. P.; Carrington, G. L.; Kapsinow, Robert; Pack, G. T., and others: Blood Concentration Changes in Extensive Superficial Burns and Their Significance for Systemic Treatment, Arch. Int. Med. 22: 31 (July) 1923.

a fall in serum proteins (7.2 to 5.4 Gm.) which took place in twenty-four hours and indicated severe capillary damage with rapid washing of blood fluids into the tissue spaces. This phenomenon must of necessity cause gross disturbances in the osmotic relations of the blood and tissues. A more complete discussion of this subject will be taken up in a later publication.

The inclusion of acacia in the intravenous fluid, as shown in protocol 3 (d), gave the most bizarre chemical picture we have observed. It appears that acacia tends to maintain the osmotic pull of the blood for a sufficient length of time to permit extreme watery dilution as a result of the continued forcing of fluids in the presence of progressive capillary leakage.

Our studies indicate that repeated transfusions of blood offer the only safe means of maintaining the blood chemical balance in the shock state. There is also an indication that blood plasma alone should be given, as the red blood cells become excessive in number. When the blood fluid balance is safeguarded in this manner other fluids may be given in moderate amounts.

The frequent observation of low blood sugar values we are not yet able to explain. It impresses us, however, that this point should be considered in the treatment of burn shock.

While these experimental studies were in progress we were called on to treat an extensive burn at the Methodist Hospital in Indianapolis. There follows a report of this most unusual clinical experience

CASE 2.—A girl aged 15 was badly burned on April 23, 1938, when her evening dress caught fire from a lighted match thrown on a ballroom floor. She was admitted to the hospital shortly thereafter, at 10:30 p. m. She was given morphine, and the charred remnants of her dress were removed. This revealed extensive burns of first, second and third degree, involving

the aid of green soap. The duration of the bath was one and a half hours. Three hours from the time of the accident she was clean and comfortable in bed with sterile sheets and dressings moistened with saline solution. Her general condition was good, but the large size of her burn gave a bad prognosis.

Our first concern was the proper balancing of her fluid intake. Blood donors were typed at once. She was given 500 cc. of physiologic solution of sodium chloride containing

Fig. 4 (case 2).—Temperature chart. Small black triangles indicate blood transfusions. In the fourth and sixth, citrated blood plasma was given. The arrow indicates the beginning of five days in an oxygen tent. The question marks on the pulse curve are explained in the report of the case.

5 per cent dextrose. Fluids by mouth were limited. She was to have a total fluid intake of not more than 3,000 cc. in twenty-four hours. Of this, approximately 1,000 cc. was to be given by mouth as liquid diet, chiefly orange juice containing dextrose, and water administered frequently in small amounts. In addition she was given calcium gluconate at frequent intervals. For her thirst she was permitted to rinse her mouth and throat as often as she desired with cool water. The remaining 2,000 cc. of fluid intake was to be administered intravenously in the form of citrated blood, physiologic solution of sodium chloride and dextrose.

The first blood transfusion was given at the end of eight hours. At this time the patient's condition was good. Her pulse, however, was soft and difficult to count with certainty. She received 500 cc. of citrated blood with 500 cc. of physiologic solution of sodium chloride. Sixteen hours later her pulse again was uncertain, and the circulation was stagnating in the burned areas. With administration of another large transfusion of blood followed by salt solution and dextrose her circulation again improved. In this manner a total of six large transfusions were given in the first four days. On each occasion additional fluids were given in the form of physiologic solution of sodium chloride, dextrose and other agents to be mentioned later. At the time of each transfusion blood was drawn for chemical study.

The urine output was never reduced to zero but definitely lagged behind the fluid intake. Daily analysis of the scanty urine showed few signs of kidney damage. The clinical course, however, was painfully stormy and difficult to control.

A few hours after her third blood transfusion the girl's condition was not good. She was flushed and plethoric, and her circulation continued to stagnate. The burned areas were progressively more edematous. Her skin was dry and hot with a temperature ranging above 104 F. There was no sign of perspiration.

The hematocrit reading was 56 per cent, the red blood count was 6,000,000 cells with 18 Gm. of hemoglobin, and the total blood proteins were 4.6 per cent.

It was this situation which suggested to us the advisability of discarding the red blood cells from the next transfusion, with the thought that blood plasma alone would best safeguard

Fig. 3 (case 2).—A girl aged 15 years who on April 23, 1938, suffered an extensive flame burn, as shown by the stippling on the photographs taken one year later. Areas of first, second and third degree burn are indicated by the density of the stipple. Calculating by the method of Berkow,¹⁰ we have estimated the burn to cover 55 per cent of the body surface.

hands, arms, neck, chest, abdomen and back, as indicated in figure 3. Her face was not injured. The deepest burns involved her arms, with which she had protected her face.

After sufficient narcosis she was placed in a tub of 1 per cent salt water at body temperature and given a bath with

10. Berkow, S. G.: A Method of Estimating the Extensiveness of Lesions (Burns and Scalds) Based on Surface Area Proportions, Arch. Surg. 8:138 (Jan.) 1924.

the fluid balance. A large amount of citrated blood was drawn and 350 cc. of blood plasma was obtained by centrifuging under sterile conditions.⁹ On April 25, forty-eight hours after the burn, this citrated blood plasma was given intravenously and in addition 600 cc. of physiologic solution of sodium chloride containing dextrose and 100 cc. containing 50 per cent sucrose, a total of approximately 1,100 cc. of fluid, which constituted the fourth transfusion. After this the patient's condition was much improved, and the edema appeared to be lessened. Her temperature, however, was difficult to control. Sudden rapid rises made us fearful of a fatal hyperpyrexia. Tepid sponging of the dry skin caused chilling with no reduction of temperature. Only by means of cool retention enemas and repeated colonic irrigations of cold physiologic solution of sodium chloride were we able to keep her temperature below 106 F.

She was able to rest only with the aid of morphine given hypodermically in one-quarter grain (0.016 Gm.) doses alternating with pentobarbital sodium $1\frac{1}{2}$ grains (0.1 Gm.) by mouth at frequent intervals.

Fig. 5 (case 2).—The girl on Oct. 6, 1939.

Eighteen hours from the time of the fourth transfusion the girl's circulation again was stagnating, but she was conscious and alert. Any manipulation caused chilling. Her temperature was persistently high and difficult to control.

With considerable apprehension another large transfusion of citrated blood was given, followed by additional fluids as before. Circulatory stasis improved, but the edema now increased rapidly and began to involve the face and other unburned areas. The patient was showing a tendency to intravenous reaction, and for this reason further effort in intravenous therapy was postponed as long as possible. Another large amount of citrated blood was drawn, however, and placed in the refrigerator in preparation for another transfusion of plasma.

For twenty-four hours the girl was closely watched until it became evident that all the symptoms just described were increasing. Her breathing was labored, and she was flushed and stuporous. The plasma carbon dioxide was 49 per cent and the total serum protein 4.2 per cent, with a hematocrit reading above 60 per cent.

Increasing edema was accompanied by progressive stasis of capillary circulation. To combat this situation the sixth trans-

fusion was given. At 8 p. m. on April 27, four days after the burn, the patient received 350 cc. of blood plasma followed by 1,150 cc. of physiologic solution of sodium chloride containing 50 Gm. of dextrose and 1 ampule of Hartmann's solution, the latter being included because of the acidosis. This transfusion, though carefully given, was followed by a chill and rapid rise of temperature, as indicated in figure 4. With a cool colonic irrigation the temperature fell.

Three hours later there was another rapid rise of temperature, to a point above 106 F. The patient became delirious for the first time and then comatose and cyanotic, with pulmonary edema. All who saw her were convinced that she would die. A few hours later she awoke rational. She was very weak, cyanotic and dyspneic. Her pulse was fast and thready. An oxygen tent was placed over her, and the condition slowly improved.

Though she remained in a critical state for several more days there was one reassuring sign. Immediately after the last plasma transfusion the edema rapidly decreased and there was a sharp increase in urinary excretion. After five days in the oxygen tent with hypodermic administration of coramine, digitalis and other symptomatic drugs, the girl's color was good and circulatory tone was restored.

It is impossible to relate all the details of symptomatic management, nursing care and the local treatment of the burned areas. Because of the distribution of her burns the patient was unable to turn or move unassisted. A special bed was constructed to permit continuous wet dressing and frequent irrigation to her burned back, on which she had to lie. During the five days in the oxygen tent an ulcer developed on the cornea of the left eye, a distressing complication. For the management of this Dr. E. W. Dyar was responsible.

One month from the time of her burn the girl was taken home. All of her large burn was healed with the exception of several granulating areas on her arms, where the burns were deep third degree. On June 1 she returned to the hospital for three days, and her granulating areas were covered with Thiersch grafts. Two months from the time of receiving her burns she was completely healed. She has remained in good health and shows no sign of constitutional impairment.

Throughout the acute burn shock reaction this case was carefully studied. At no time did the systolic blood pressure fall below 80 mm. of mercury. At no time was the patient pulseless, although many times we could not be certain of the actual pulse rate. At these times transfusions of blood or blood plasma together with the intravenous fluids were administered. At no time was there complete anuria. During the period of her greatest edema, however, the urine output lagged far behind the fluid intake. A complete tabulation of laboratory data would be laborious and is unnecessary. With the exception of the abnormal values previously mentioned in the report, the numerous blood chemical and other laboratory reports give little or no indication of the stormy clinical course.

It is evident that this girl was in a grave state of burn shock for five days. We believe that a state of irreversible shock was prevented and that her life was saved by the repeated intravenous administration of properly balanced fluids, the most important components of which were blood and blood plasma.

Other significant therapeutic measures were the administration of oxygen, the control of temperature, proper sedation and the local treatment of her burns with mild antiseptic wet dressings and the scarlet red ointment preparation of Bettman.⁵ At no time did sepsis complicate her recovery.

COMMENT

Extensive burns present extremely complex problems in management. In this report we have related two cases, in addition to experimental observations, which

9. Drs. K. E. Thornberg, R. G. Fry and Horace Banks, pathologist, Methodist Hospital, prepared the citrated blood plasma.

have given us a new conception of the burn shock reaction. Our views, furthermore, are substantiated by numerous less complete clinical and experimental studies carried on by one of us (H. M. T.) over a period of ten years.

We are convinced that the successful treatment of burn shock depends on systemic measures and that the local treatment has little or nothing to do with this phase of the problem. There is no reason to believe that the local application of tannic acid or any other agent to the burned area is effective in preventing burn shock or in protecting the fluid balance of the body. It is unfortunate that for so many years this thought has confounded the essential requirements for burn shock therapy. Case 1 of this report shows an excellent example of this fallacy. In this instance a sterile tanned membrane was applied within two hours of the burn under ideal conditions. The patient died in convulsions on the third day.

Case 1 demonstrates in dramatic fashion what may happen to the blood chemistry when improperly balanced fluids are forced into a patient who is in a state of inflammatory shock due to an extensive burn. This baby received excessive amounts of fluids, chiefly in the form of water by mouth. The amazingly low blood chloride reading at death indicates to us a condition of water intoxication complicating burn shock. Our experimental studies substantiate this view.

We wish to emphasize the fact that the blood chemical values and the clinical course of patients in burn shock depend chiefly on the manner in which fluids are administered. Maintenance of fluid balance under such conditions presents a problem entirely different from that of the relatively simple fluid therapy required for patients who are merely dehydrated. The difference lies in the fact that burn shock results from a mechanism which causes stagnation of the circulating blood and a rapid loss of blood fluid through capillaries which are leaking into the tissue spaces. Under these conditions the forced administration of fluids is futile or even dangerous unless the blood chemical relationships are protected by repeated transfusions of blood or blood plasma.

As to prognosis and treatment, burns can be classified in three groups:

1. Relatively slight burns, in which shock is not a problem. The normal mechanisms of fluid and chemical balance may protect the patients sufficiently to permit recovery under any plan of systemic treatment or with no treatment at all.

2. Hopelessly extensive burns, in which no treatment will succeed in saving the lives of the patients.

3. Burns of critical degree, with the outcome depending greatly on the treatment; in these cases life may actually be saved by a rational therapeutic regimen.

Case 2, we believe, is an example of the third group.

In the fourth and sixth transfusions blood plasma was given with beneficial results, as previously discussed. It is interesting to note that the girl's total blood protein fell as low as 4.2 per cent, even though repeated transfusions were given. There was also a persistent acidosis; in addition the heat-regulating mechanism was profoundly disturbed, with absence of perspiration and hyperpyrexia. The patient's recovery may be explained by the fact that the fluid balance and blood chemical relationships were maintained sufficiently near normal to sustain life throughout the self-

limited period of the acute burn shock reaction. The importance of oxygen therapy should be emphasized.

It is important that burn shock be anticipated and treated by complete control of all phases of the case and by the administration of properly balanced fluids from the beginning. Any therapeutic effort is futile when once the shock state becomes irreversible.

The local treatment of large burns should be instituted entirely with the thought of preventing infection and providing for rapid healing. The importance of this is obvious, but further discussion of our views on local treatment does not come within the scope of this publication.

There are variable factors in the burn shock reaction which at present are somewhat obscure. The question of burn toxins we are not discussing at this time except to emphasize that the mechanism of death in so-called burn toxemia is secondary circulatory shock due to diffuse inflammation.

SUMMARY

1. The tannic acid theory of the treatment of burns is fallacious. There is no local application that can be expected to save life after a large burn.

2. The first cause of death due to the extensive burn is shock. There are two phases in the burn shock reaction.

- (a) The traumatic phase: Circulatory shock due to vascular stasis and the loss of blood plasma, which escapes into the tissue through capillaries injured by heat. Very large burns may be rapidly fatal by this mechanism.

- (b) The inflammatory phase: A complex syndrome in which the loss of fluid is accompanied by the other morbid processes of diffuse thermal inflammation. This accounts for the toxic manifestations.

3. The blood chemical changes of the shock state depend largely on the manner in which fluids are administered. The indiscriminate forcing of simple fluids into a burned patient is futile and may lead to profound disturbances in the physical-chemical relations of the blood.

The persistent forcing of water by mouth under these conditions may cause a fatal water intoxication.

4. The successful treatment of burn shock calls for a complex therapeutic regimen. Blood transfusions should be given early and repeated frequently throughout the self-limited period of the reaction. Other fluids should be given in moderate quantities. Large amounts of dextrose are indicated.

5. In case 2 of this report recovery followed the giving of six large blood transfusions in four days. Because of polycythemia, in the fourth and sixth transfusions citrated blood plasma was given. The importance of oxygen therapy should be emphasized.

1040 West Michigan Street.

Relief from Mosquito Bites.—Mosquito bites, while perhaps never serious in themselves, may lead to blood poisoning through scratching with the fingernails in the attempt to relieve the irritation, which is often intense. To relieve this irritation any one of the following may be applied, viz.: ammonia, glycerin, alcohol or iodine. According to Howard the most satisfactory remedy known to him is the application of moist toilet soap. He also mentions touching the puncture with a lump of indigo as affording instant relief, or touching the parts with naphthalene moth balls.—Hermes, William B.: *Medical Entomology*, New York, Macmillan Company, 1939.

THE TREATMENT OF SYPHILIS WITH SOBISMINOL MASS GIVEN BY MOUTH

WILLARD M. MEININGER, M.D.

AND

CHARLES W. BARNETT, M.D.

SAN FRANCISCO

The treatment of syphilis would undoubtedly be facilitated by the discovery of a bismuth preparation which is effective when taken by mouth. Proper anti-syphilitic therapy, when the medication is given by injection, requires frequent visits to the physician over a long period of time. Many patients discontinue their treatment prematurely or receive it at very irregular intervals because of the inconvenience of these visits or because of the pain of intramuscular injection. If a suitable oral bismuth preparation were available the attendance could safely be reduced and the pain of intramuscular injection avoided. It would be possible to continue anti-syphilitic therapy during periods when regular visits to the physician are not feasible or for patients who experience reactions to intramuscular therapy. Several bismuth preparations designed for oral administration have been tried without conspicuous success. In 1937 Hanzlik, Lehman and Richardson¹ introduced a product called sobisminol into the therapy of syphilis. This drug may be administered either orally or intramuscularly, and the purpose of the present paper is to report the clinical results obtained with sobisminol mass when given by mouth.

Sobisminol mass² is given in capsules, each containing 0.2 Gm. of sodium bismuthate, 0.4 Gm. of triisopropanolamine and 0.1 Gm. each of propylene glycol and ethyl alcohol. The bismuth content of each capsule is 0.15 Gm. Hanzlik and his staff³ have shown that this product is readily absorbed from the gastrointestinal tract in experimental animals and also in man. They have demonstrated that it is well tolerated in doses sufficient to produce and maintain a urinary excretion equal to or greater than that usually obtained with intramuscular injections of bismuth. These observations, which were confirmed by Sollmann, Cole and Henderson,⁴ indicate that sobisminol mass should be a potent anti-syphilitic agent. The clinical effects of this preparation have been reported only with regard to disappearance of surface spirochetes and the healing of cutaneous lesions. In these respects it was highly satisfactory.

Syphilis is a chronic infectious disease in which the prognosis without treatment is practically unknown but which often remains entirely asymptomatic throughout

life. Since the final criterion of the effectiveness of any therapeutic agent is the ultimate clinical outcome, it is impossible to evaluate any anti-syphilitic drug completely without an observation period of many years. We are therefore forced to rely on less adequate criteria. However, these do become of greater value with a longer period of observation. Sobisminol mass has been used in the syphilis clinic of the Stanford University Medical School for the last three years. During this time we have been able to evaluate in some respects the therapeutic effect of this preparation, but we do not feel that we have finally assessed its true worth.

There were 143 patients whose records were complete enough to be of use in the evaluation of sobisminol mass. In an additional forty-nine patients only data on tolerance were obtained. Each patient attended the clinic at intervals of one or two weeks, at which time he was carefully questioned as to tolerance and the clinical response was noted. Every effort was made to determine at each visit the exact number of capsules ingested during the preceding interval from the patient's story and the number of capsules dispensed. The daily dose estimated in this way is much nearer to the amount actually ingested than the prescribed dose would be. In this report the estimated dose will be used unless the prescribed dose is specified.

TABLE 1.—The Concentration of Bismuth in the Urine with Various Doses of Sobisminol Mass When Determinations on Separate Single Specimens Are Averaged

Sobisminol Mass Ingested (Grams per Day)	Mean Excretion (Milli- grams per Liter)
0.26 to 0.75.....	3.1
0.76 to 1.25.....	2.6
1.26 to 1.75.....	3.2

It would be desirable to have another more objective method of determining the amount of sobisminol mass taken, and measurement of the amount of bismuth excreted in the urine has been suggested for this purpose. Such determinations should be done on the total urinary output, but this is not feasible in ambulatory patients who make only occasional visits to the doctor. It is therefore necessary to rely on single specimens in the hope that the concentration of bismuth in these may parallel the total excretion and indicate the amount of sobisminol mass ingested. Hanzlik⁵ and Sollmann⁴ and their co-workers demonstrated an increase in the average amount excreted with higher doses, but both observed wide daily variations.

All our patients were requested to leave specimens of urine for bismuth analysis on every visit to the clinic. The bismuth determinations were carried out in the department of pharmacology by Dr. A. J. Lehman and Dr. Walton Van Winkle Jr., first by a long quantitative method⁶ and later by a shorter clinical method.⁷

The concentration of bismuth in single specimens of urine ranged between 0 and 24 mg. per liter. Individual observations varied widely in different patients and also

7. Hanzlik, P. J.; Lehman, A. J.; Richardson, A. P., and Van Winkle, Walton, Jr.: Rapid Clinical Method for Estimation of Bismuth in Urine, *Arch. Dermat. & Syph.* 36:723 (Oct.) 1937.

in repeated specimens from the same patient. Practically all patients submitted occasional specimens of urine entirely free of bismuth even though they were apparently taking sobisminol mass regularly. Bismuth determinations in single specimens of urine proved to be of no practical value in estimating the amount of sobisminol mass ingested, nor could they be relied on to detect whether or not the drug was being taken.

Since single specimens of urine seemed of no value, we have averaged the urinary bismuth concentrations when multiple observations were made on the same patient. There were 118 individuals with from five to seventy-five separate determinations, the total number being 2,442, an average of 21 per patient. The results are shown in table 1.

It is evident from table 1 that the concentration of bismuth in urine is of no value in determining whether or not sobisminol mass is being ingested. This, of course, has no bearing on the correlation between ingestion and excretion, which has been demonstrated by Hanzlik³ and Sollmann,⁴ since in our study only occasional single specimens of urine instead of the total output were utilized.

Bismuth determinations were done on thirty specimens of blood, practically all from patients on a prescribed dose of 1.8 Gm. a day. The bismuth content varied from 0 to 0.16 mg. per hundred cubic centimeters, but twenty-one of these specimens contained less than 0.01 mg. per hundred cubic centimeters. There was no apparent relation between the bismuth in the blood and the therapeutic effect.

During the early part of the study the prescribed dose of sobisminol mass was 0.6 Gm. a day (one capsule three times a day). This amount was well tolerated and it was increased later to 1.2 Gm. (two capsules three times a day) and 1.8 Gm. a day (three capsules three times a day). We believe that 0.6 Gm. is inadequate, although it was taken by too few patients for us to be sure. The optimal dose appears to be 1.2 Gm. a day. A larger quantity had no greater therapeutic effect and was not as well tolerated. Moreover, when a dose of 1.8 Gm. was prescribed this amount frequently was not taken. In more than one third of the patients given this dose the amount actually taken was less than 1.2 Gm. When 1.2 Gm. was prescribed, only one sixth of the patients took less than 1 Gm.

Sobisminol mass was well tolerated by almost all patients and no really serious reactions occurred. Thirty-seven per cent of 192 patients experienced some degree of reaction to the drug. Mild gastric disturbances were the commonest reactions, constituting 68 per cent of the total. These occurred most commonly during the first week and consisted of a feeling of fullness in the epigastrium or a sensation of hunger, occasionally accompanied by nausea and vomiting. Most patients noticed a slight increase in frequency of bowel movements but only 6 per cent actually had diarrhea. In five patients a bismuth line developed. Four others had an acute stomatitis which came on during the first few days of medication, disappeared rapidly following withdrawal of the drug and did not recur when it was resumed. An occasional patient after taking a capsule with insufficient water experienced a severe burning sensation in the esophagus that persisted for several days. A pityriasis rosea-like eruption, probably due to bismuth, occurred in three patients, and another had a toxic erythema for which no other cause could be found.

Urinalyses were made at frequent intervals and in no case was there any suggestion of renal damage. Liver function tests were not done, but there was never any clinical evidence of hepatic damage. Sobisminol mass was discontinued in five cases on account of severe gastrointestinal reactions and in five more intramuscular bismuth was substituted because we were convinced that the drug was not being taken with any degree of regularity.

The tolerance of a drug having been established, its therapeutic efficiency must be investigated. The effect of an antisyphilitic agent may be appraised in a few days by the rapidity with which it causes spirochetes to disappear from surface lesions in early syphilis. It can be estimated within a few weeks by the rate of

Fig. 1.—The appearance of lesions on the back in secondary syphilis Nov. 27, 1936.

involution of benign tertiary and early cutaneous lesions. It may be measured over a period of months by the symptomatic response in late syphilis, but only by the ultimate outcome as determined over a period of many years can it be proved.

The rapidity with which sobisminol mass caused *Spirochaeta pallida* to disappear from surface lesions was observed in thirty-three cases of seropositive primary or secondary syphilis in which neoarsphenamine was withheld for a period of two weeks. We did not feel justified in using sobisminol mass alone in seronegative primary syphilis, even for a brief period, because the prognosis is definitely better when treatment is started before the serologic reactions become positive. However, two patients failed to return for serologic reports and received only sobisminol mass for eight and ten days. The serums of both were then strongly positive. In the patients who were followed for dark field reversal, careful examinations were made on at least three prep-

arations each day. These examinations were continued in nearly every case until results of dark field examinations were negative on three successive days. No local medication was used. A few patients were given 0.6 or 1.2 Gm. of sobisminol mass daily, but 1.8 Gm. was prescribed for the majority and the average time required for the disappearance of *Spirochaeta pallida* was 4.2 days in twenty-nine cases. In the other four the result of dark field examination was still positive on the fourteenth day when neoarsphenamine was started.

The rate of involution of the lesions of early syphilis with sobisminol mass was observed in fifty-one cases. Fourteen were in the primary and thirty-seven in the secondary stage. Eleven primary lesions were completely involuted in from two to fourteen days, the average being 10.3 days. In each of the other three the involution was estimated at 90 per cent at the end of fourteen days. The secondary lesions in twenty-six cases were entirely healed in from four to fourteen days, with an average of 10.4 days. In eleven other cases the lesions had not completely healed at the end of fourteen days when neoarsphenamine was begun. At this time the average degree of involution was estimated as 70 per cent. An example of complete involution of psoriasiform secondary lesions after

Fig. 2.—Appearance of lesions shown in figure 1 December 9, showing healing after treatment with sobisminol.

twelve days of sobisminol mass alone with an average dose of 1.65 Gm. daily is shown in figures 1 and 2. The residual pigmentation, evident in figure 2, often persists for months and was disregarded in determining involution.

The rate of involution of various types of late cutaneous lesions was determined in twenty-eight cases. Healing was complete in from one to twelve weeks,

with an average of 4.4 weeks. Since the lesions were observed at weekly intervals, the true average is probably slightly less than this. The rate of disappearance was dependent on the amount of induration and destruction and consequently varied widely. On the whole, the response was extremely satisfactory. An example of involution in a deeply ulcerated gumma is shown in

Fig. 3.—The appearance of lesions in tertiary syphilis, Oct. 15, 1936.

figures 3 and 4. At the time figure 4 was made the patient had taken an average of 1.75 Gm. of sobisminol mass daily for six weeks without other therapy.

A summary of the data on the rate of involution of lesions under sobisminol mass therapy is given in table 2.

About half of the patients were given 1.8 Gm. of sobisminol mass daily and the other half 1.2 Gm., with the exception of a very few who took 0.6 Gm. There was no discernible difference in the time of dark field reversal or of involution between any of these groups.

In seventy-three cases of late syphilis, including those presenting cutaneous lesions, treatment was initiated with sobisminol mass and was continued without other antisypilitic therapy for an average period of 4.7 months. Twenty-three patients took it for more than six months and seven for more than one year. A serologic reversal occurred in three cases, in one at four months and in another at seven months. In the third the Wassermann reaction was two plus after ten months of sobisminol mass, at which time treatment was discontinued, and the Wassermann reaction was negative three months later.

In a number of patients with late syphilis of the cardiovascular or nervous system there seemed to be subjective improvement with sobisminol mass. However, when oral medication is used instead of intramuscular injection, about which patients are likely to be quite apprehensive, one hesitates to ascribe subjective improvement to the action of the drug.

In late syphilis the only indexes of therapeutic efficiency that can be obtained in a short time are the

involution of lesions, a Wassermann reversal and subjective improvement. Many years is required for the true evaluation of an antisyphilitic drug because of the extremely variable course of the disease, and the final effect of treatment can never be determined until death has occurred.

The final result in early syphilis is even more remote than in late, but certain clinical or serologic events may occur that will permit earlier evaluation of a drug. The most important of these events are Wassermann fastness, involvement of the central nervous system and serologic or clinical relapse. When these occur during treatment or after apparently adequate treatment, their frequency is a valuable index of the effectiveness of therapy.

When oral bismuth was first used, it was decided to follow the same plan of treatment for early syphilis then in effect in the clinic, except for the replacement of iodobismutol by injection with sobisminol mass by mouth. According to this plan, neoarsphenamine and iodobismutol were given simultaneously once a week for twenty weeks. Neoarsphenamine was then omitted for five weeks, after which a second course of twenty injections was given. The initial course of iodobismutol was

TABLE 2.—*The Rate of Involution of Syphilitic Lesions in Patients Treated with Sobisminol Mass*

No. of Cases	Diagnosis	Involution Complete	Average Time for Involution	Per Cent Involution in Lesions Still Present at 14 Days
11*	Primary	1-14 days	10.3 days	90%
3	Primary			
26	Secondary	4-14 days	10.4 days	70%
11	Secondary			
28	Tertiary	1-12 weeks	4.4 weeks	

continued to thirty doses and a second course of forty doses was given after an interval of five weeks. The usual dose of neoarsphenamine was 0.45 Gm. for both men and women, and that of iodobismutol was 2 cc. In the present series, instead of weekly injections of iodobismutol, sobisminol mass was given by mouth in divided daily doses of 1.2 or 1.8 Gm. during corresponding periods. The only other deviation from the original plan was the two week period in which some of the patients received sobisminol mass alone, prior to the administration of neoarsphenamine. The scheme of treatment is shown here diagrammatically, in which the figures indicate the number of weeks.

Ninety-three patients with early syphilis were given this type of therapy. Thirty-six were in the primary stage, seventeen being seronegative. Fifty-four had secondary lesions and three were early latent. Thirty-nine of these patients were followed for more than a year, nineteen for more than eighteen months but only five for more than two years. The average total period of observation was eleven months. Seventy-four were followed for more than five months and the results in these may be compared to the results that were reported by Beckh and Barnett⁸ in a similar series in which iodobismutol was administered.

There were only thirty-six patients who were initially seropositive and whose Wassermann reactions of the blood were repeated at five months, permitting comparison with the iodobismutol series. Thirty-one of these, or 86 per cent, became negative. This figure compares quite favorably with that obtained by similar treatment with iodobismutol, in which forty-six of fifty-eight, or 79 per cent, became negative.

TABLE 3.—*The Incidence of Serologic Reversal and of Cerebrospinal Fluid: Abnormalities Obtained with Sobisminol Mass Therapy in Comparison with That Obtained by Similar Treatment with Iodobismutol*

	Type of Bismuth	
	Sobisminol Mass	Iodobismutol
Number of patients.....	36	58
Seronegative at 5 months.....	31 (86%)	46 (79%)
Number of patients.....	51	43
Positive cerebrospinal fluids.....	2 (4%)	7 (16%)

The cerebrospinal fluid was examined at some time during the course of treatment in fifty-one cases. None of these showed any clinical evidence of involvement of the nervous system and only two had positive reactions of the spinal fluid. These were examined approximately six months after the beginning of treatment. Both showed a moderate pleocytosis and a slightly elevated protein content. The Wassermann reactions were positive with 1 cc. of fluid but negative with smaller quantities, and the colloidal gold curves were normal. In the series treated with iodobismutol, seven of forty-three spinal fluids gave positive reactions. These results indicate that sobisminol mass may prove to be of value in the prevention of neurosyphilis.

The incidence of serologic reversal and of cerebrospinal fluid abnormalities obtained with sobisminol mass

therapy in comparison with that obtained by similar treatment with iodobismutol is summarized in table 3.

Even though the series is small, the figures in table 3 suggest that sobisminol mass is superior to iodobismutol in producing a Wassermann reversal and preventing involvement of the nervous system.

In the present series of seventy-four patients there were several who relapsed during treatment. The incidence of these relapses in comparison with that observed under similar treatment with iodobismutol is shown in table 4.

8. Beckh, Walter, and Barnett, C. W.: The Effect in Early Syphilis of Combined Treatment in Comparison with Alternating Treatment, *Arch. Int. Med.* 63: 974 (May) 1939.

Of the patients who relapsed under sobisminol mass therapy, typical cutaneous secondary lesions developed in five. Two of these had recurrences of positive Wassermann reactions coincident with a relapse, and a third was Wassermann fast. No serologic data were obtained in the other two. A positive dark field examination was obtained in only one of these patients, but all lesions involuted promptly after modification of treatment and there can be little doubt as to the accuracy of the diagnosis. In the other three cases the relapse consisted of an acute iridocyclitis. In one there was a recurrence of a positive Wassermann reaction at the time of relapse. In the other two there may be some doubt as to the diagnosis of relapse, since in one no serologic reaction was obtained and in the other the Wassermann reaction remained negative.

From table 4 it appears that the incidence of relapse is approximately the same with the two types of therapy. If the two series differed only in the bismuth

Fig. 4.—Appearance of lesions shown in figure 3 November 25, showing healing after treatment with sobisminol.

preparation used, this conclusion would be justified. There is, however, another important difference, namely the time of observation. It is improbable that many more relapses will occur in the iodobismutol group, since the majority of recurrences in early syphilis appear within two years after infection, and two years has elapsed since iodobismutol was replaced by sobisminol mass in this type of therapy. On the other hand the patients receiving sobisminol mass are still within the period of potential relapse and more clinical or serologic recurrences may be expected to appear in this group. When one considers that the average time of relapse after treatment was begun in the iodobismutol group was eighteen months and that the average total period of observation in the sobisminol mass series is only eleven months, such recurrences must be anticipated. Moreover, in the latter group only seventeen have been followed for as long as eighteen months, and of these two have already had a relapse. If the period of observation were longer, sobisminol mass would probably compare less favorably with iodobismutol in the prevention of relapse than is indicated in table 4.

In those patients who did have a relapse, an attempt was made to discover a possible explanation. Each patient was repeatedly questioned regarding the number of capsules taken, and this was checked with the amount dispensed. In no case could we prove that the drug was not being taken regularly. The excretion of bismuth in the urine was well within the average limits in every patient. There was no evident relationship between the incidence of relapse and the age, sex, diagnosis, regularity of treatment, amount of neoarsphenamine or dose of sobisminol mass. Except for the bismuth product itself, the only factor that seemed to be of importance in the production of relapse was the treatment pattern employed.

In the report of Beckh and Barnett,⁸ it was shown that this combined type of treatment was productive of more relapses than a simple alternating type, even when the same bismuth preparation was used. Had we been aware of this at the time the present study was planned, sobisminol mass would have been used in alternating courses with neoarsphenamine. However, since the present treatment was identical with the combined type except for the substitution of sobisminol mass for iodobismutol, the probable higher incidence of relapse with sobisminol mass must be ascribed to the drug and not altogether to the type of therapy.

There are obvious disadvantages in the oral treatment of syphilis. When treatment is given by injection, the physician knows not only that the patient has received the medication but the amount injected and the time of administration. When it is given orally the control is entirely in the hands of the patient, and the physician has only his word that the drug is even being taken. This disadvantage of oral medication is important in the treatment of syphilis because prolonged and uninterrupted treatment is essential. Even intelligent and conscientious patients will often admit irregularities in ingestion after a few weeks or months. Although the great majority of patients prefer oral therapy, there are a few who have little discomfort after intramuscular injection and consider frequent oral medication a nuisance. There is also the danger that the release of an effective antisypilitic drug which can be taken orally may lead to self medication.

In spite of the disadvantages, there is a definite place in the treatment of syphilis for an effective oral bismuth preparation such as sobisminol mass. Continuous treatment is essential in early syphilis and of considerable importance in late syphilis. Sobisminol mass provides a means of preserving continuity in treatment when regular visits to the physician are impossible or when severe reactions make intramuscular administration unpractical.

SUMMARY

Sobisminol mass is well tolerated when taken by mouth in therapeutically effective doses. It produces rapid involution of lesions in early and benign late syphilis and causes the disappearance of spirochetes from the surface lesions of early syphilis. It appears to reduce the incidence of involvement of the nervous system but does not prevent a clinical or serologic relapse when substituted for intramuscular bismuth in the treatment of early syphilis. It is a valuable addition to antisypilitic therapy and certainly deserves further clinical trial.

SOBISMINOL MASS: CLINICAL RESULTS
WITH ORAL ADMINISTRATION

JULIUS R. SCHOLTZ, M.D.

KATHERINE D. McEACHERN, M.D.

AND

CLYDE WOOD, M.D.

LOS ANGELES

This report represents the results of the first eighteen months of our experience in the clinical use of a bismuth preparation for oral administration (sobisminol mass),¹ which has been made available through the cooperation of Professor Hanzlik of Stanford University.² It was supplied in capsules containing the reaction product of sodium bismuthate 0.2 Gm., triisopropanolamine 0.4 Gm., propylene glycol 0.1 Gm. and ethyl alcohol 0.1 Gm. This represents approximately 150 mg. of elemental bismuth. We now report clinical results in ninety cases, including cases of seropositive primary, secondary, late benign (bone, skin, mucous membrane), central nervous system (tabetic, meningo-vascular) and congenital syphilis.

GENERAL CONSIDERATIONS IN ORAL VERSUS
INTRAMUSCULAR THERAPY

There are many obvious facts which make oral administration preferable to any other type as a therapeutic procedure, but with diseases such as syphilis, because of the nature of the drugs which must be used, certain singular problems arise which require special consideration.

One of the most important major objections to oral therapy with drugs whose absorption from the gastrointestinal tract is not complete and consistent is that, since the exact amount mobilized for the circulation and tissues is not determinable, oral administration is inaccurate and is dangerous from the standpoint both of overdosage and toxicity and, with syphilis, of the opposite danger, i. e. inadequate dosage, with its well known consequences. This objection is serious and valid and deserves careful consideration.

The same criterion, however, must be applied in examining bismuth preparations used by other routes. Intravenous administration of completely soluble drugs satisfies our requirements nicely, but, on the other hand, intravenous therapy has many fundamental dangers and it is well established that intravenous administration of bismuth raises the toxicity of the drug to such a point that its use is impossible.

Let us examine, then, the conventional intramuscular administration of bismuth from the standpoint of the criterion which we applied to the oral administration of drugs.

We find that, with the exception of a few of the highly soluble preparations, most of the preparations in common use leave varying quantities at the site of injection and that in some cases, because of local reac-

tions and encapsulation or the formation of salts, the quantity may be large. We find then that, although we do know the exact amount of the drug introduced into the body, we do not know the exact amount actually mobilized in an active form. It is therefore possible to have gross underdosage with certain compounds for intramuscular administration and, in certain instances, the storage and accumulation of quantities of the drug which might under certain conditions result in serious intoxication. We find that our main objection to oral therapy with partially absorbable drugs applies equally strongly to partially absorbable drugs given into the muscle and that the depot type of treatment is far from the ideal pharmacologically.

It seems therefore that so far as accuracy is concerned (and for the present without regard for the peculiar requisites of the desirable drug in the treatment of syphilis) the drug which is completely tissue soluble is the drug of choice for intramuscular therapy and that a drug whose absorption from the gastrointestinal tract is consistent and quantitatively known is equally desirable for oral therapy.

If two such drugs were available and were shown to be equally effective in therapeutic activity, the choice would be determined by balancing the advantages and disadvantages inherent in the intramuscular route against those of the oral route. It is unnecessary to enumerate the objections to intramuscular injection, but it immediately becomes obvious that, all other things being equal, the oral route of administration is the desirable one.

ROLE OF BISMUTH IN THE TREATMENT
OF SYPHILIS

When one begins to consider the role of bismuth in the treatment of syphilis, certain factors appear which immediately make the problem of the choice of drug and the route of administration much more complex than was indicated in the previous section.

It has been generally considered that of all the attributes of the heavy metals the most important is their capacity to "build resistance" or stimulate the "defense mechanism." Thus far the knowledge of this phenomenon is meager and is best described as nebulous. Possibly a more concrete conception is to interpret this mechanism as one of "relapse prevention." Regardless of the fact that knowledge of the mechanism is slight, the observable fact remains that the important function of bismuth is not in killing spirochetes but in reinforcing the therapeutic attack in some way which makes the human organism better able to consolidate the gains brought about by the arsenical drugs. If it can be shown therefore that this effect of bismuth is altered by or in any way connected with the route of administration, it becomes apparent that the problem is not simply the question of getting a given amount of bismuth into the circulation.

One obvious question is immediately raised: Is the relapse-preventing effect of bismuth due to the fact that the depot in the muscle represents a long time supply of small quantities of previously unmobilized bismuth, or is the effect brought about by the bismuth which has been deposited in body tissues and fluids in combination with serum proteins? The answer to this question would be of greatest value in the solution of the bismuth problem. Excretion studies by many different investigators have shown that, almost regardless of the type of bismuth preparation given by muscle, approximately

From the Department of Medicine (Dermatology and Syphilology), University of Southern California School of Medicine, and the Syphilis Clinic of the Los Angeles County Hospital.

2. E. R. Squibb & Sons supplied the drug.

50 per cent of the drug administered is retained in the body after the initial period of appreciable excretion and that the retained portion is excreted in almost immeasurable quantities over a prolonged period. This seems to be true even of those highly absorbable drugs which are known to leave the injection depot almost completely within a very short period (days or weeks). During the period of appreciable excretion, therapeutic activity such as spirocheticidal effect is easily demonstrated. The period of prolonged minor excretion (many months) is the period about which little is known but which may be the crucial and significant one. In this period the bismuth is distributed to the tissues and tissue fluids and is present in minute quantities, and it is here that it may play its essential role of apparent stimulation of defense or resistance or act to prevent relapse.

It would seem therefore that this effect is due to the peculiar fact that bismuth tends to be remobilized and excreted very slowly from the tissues in which it has been distributed rather than to the fact that there is a long time depot supply. Assuming this to be acceptable it then seems that, so long as the bismuth is absorbed into the circulation and distributed to the tissues and tissue fluids in adequate amount, neither the type of preparation nor the route of administration is of fundamental importance.

The classic experiment of Kolle would suggest that such a conclusion is incorrect and that bismuth is effective only when freshly mobilized from a depot and exerts a spirochetostatic effect only so long as the depot remains in place. This would indicate that the bismuth in tissue and tissue fluid has no therapeutic effect. Levaditi is of the opposite opinion and supports the contention which we have outlined. In the meantime the question is not answered, so that we cannot make a choice on the basis of known pharmacodynamic facts.

We must turn therefore to clinical results and methods. These methods represent after all the ultimate answer to therapeutic questions but with syphilis require many years for a complete answer. In this particular situation it must require a minimum period of five years to show the ultimate therapeutic results attained by incorporating the several bismuth compounds into an otherwise similar treatment system, and only by careful study of the results of treatment can the final choice be made as to which type of bismuth is superior or whether all types are equally acceptable.

In the meantime the individual clinician must decide whether he wishes to accept new drugs and methods which show great promise but which are yet unproved, or to continue using drugs and methods which admittedly can be improved but which time has shown can produce a degree of therapeutic success.

CLINICAL RESULTS OF ORAL ADMINISTRATION

Our first reaction to the use of bismuth by mouth was that, if it should prove equally effective therapeutically, the obvious advantages would make this method of treatment the one of choice. After our brief experience with this type of treatment we gained the following definite impressions:

Advantages:

1. The majority of patients prefer taking capsules by mouth three times a day to intramuscular injection once a week.
2. The drug can be used by persons who do not absorb bismuth from the muscle.
3. Apparently no depots are formed, and we did not find any evidence of cumulative toxic effects.

4. Management of a large number of patients in the clinic would be greatly facilitated and probably less expensive, since no apparatus for treatment is required.

5. Patients tend to be more regular in their treatment because many of them greatly fear the injection, with its attendant pain and discomfort.

6. Treatment accidents such as abscess and embolism are precluded.

Disadvantages:

1. The success of the treatment is directly dependent on the intelligence and cooperation of the patients, many of whom forget or neglect to take their capsules regularly because of various unimportant reasons.

2. A small number of patients are unable to tolerate treatment by mouth because of serious gastric intolerance.

3. There is a rather high incidence of gastrointestinal reaction which, although mild, tends to discourage patients during the early weeks of treatment.

4. Because of absence of depots, this method of treatment does not have any sustained effect, as shown by the fact that several patients with early involvement showed relapses within two weeks after treatment was discontinued.

5. The fundamental objection to all oral treatment holds true here, i. e. that the amount of the drug actually assimilated is not easily determined and apparently varies from day to day, depending on the functional state of the gastrointestinal tract.

Dosage: Early in this study we used nine capsules of sobisminol mass daily as a standard dose. This represented 1.25 Gm. of bismuth. Later on it was found that six capsules, or about 0.84 Gm. of bismuth, daily seemed to be just as effective therapeutically and to be somewhat better tolerated, and this was used as the standard dose thereafter.

DESIDERATA FOR NEW BISMUTH COMPOUND

Keeping in mind that the prime criterion by which to judge a drug in the treatment of syphilis is the ultimate long time results, as suggested previously, but unable because of certain circumstances operating in this clinic to incorporate bismuth given orally into our treatment of early syphilis as the sole heavy metal, we have had to content ourselves with observing its effects in relation to the following points:

1. Does it reach the blood stream and tissues in active form in adequate amount? This was studied by observing the effects on active observable lesions of all types.

2. How well is it tolerated and what are its toxic effects?

3. Does it have a sustained optimum therapeutic effect? This we consider to be demonstrated by sustained effect for an appreciable period after the administration of the drug was discontinued.

We have considered that the circumstances under which we have studied the drug did not allow for a significant effect on serologic reactions and therefore do not include such effect in the report.

We have chosen to demonstrate question 1 in the following manner:

Patients with seropositive primary and with secondary syphilis were given sobisminol mass orally as the initial treatment, and this treatment was continued for two weeks without the addition of any other drug. At the end of two weeks, treatment with an arsenical was begun regardless of the state of involution of the active lesion, since it was felt that any further delay would jeopardize the prognosis. On the other hand, active late benign lesions of the bones, skin and mucous membrane were allowed to go for several months if possible to allow for complete involution. Certain elderly persons with late latent syphilis and late neurosyphilis (ad-

quately treated) have also been allowed to continue with the drug for many months. Evidence of activity of the drug was measured by the rate of involution of the lesions as compared with the natural involution and that achieved with other drugs. Patients with symptomatic late neurosyphilis were chosen also to show that the drug could bring about relief of symptoms. Although these results are not objective in any sense of the word, the conditions under which results were measured allow us certain conclusions, which will be discussed later.

Question 2, on toxicity and reactions, was studied with simple statistical analysis in the usual manner.

Question 3, on evidence of sustained effect, is difficult of evaluation and probably must be interpreted differently with early and with late syphilis. From the clinical standpoint we considered that relapse and reactivation during treatment or soon after its cessation were evidence of lack of sustained effect. It should be noted that so many factors enter into this situation that any conclusions drawn are subject to question.

RESULTS OF TREATMENT

There were five cases of seropositive primary syphilis, twenty-seven cases of secondary syphilis (all types represented), twelve cases of late benign syphilis of the bones, skin and mucous membrane, twenty-three cases of syphilis of the central nervous system (mainly tabetic and meningovascular) and twenty-three cases of latent syphilis (early and late).

Seropositive Primary Syphilis.—The average period of involution was fourteen days, with extremes of ten and twenty days. The results of darkfield examination became negative in from two to eight days (average five days). Stained³ biopsy material from the lesions showed that spirochetes were present as long as twelve or fourteen days after treatment was started in some instances and long after the results of darkfield examination were negative. The spirochetes, however, were in a fragmented and deteriorated form.

Secondary Syphilis.—Of the twenty-seven patients, five were not treated to complete involution for several reasons. One responded well but on the sixth day had severe pyralism and treatment with sobisminol mass was discontinued. With the other four there was an average of 80 per cent (90, 90, 70, 60) involution in fourteen days. In twenty-two there was complete involution in an average of twelve days. This group was divided as to dose, ten patients receiving six capsules (about 0.84 Gm. of bismuth) daily and twelve receiving nine capsules (1.25 Gm. of bismuth) daily. The first group averaged 12.6 days and the second group 11.6 days for complete involution.

The slight increase in effectiveness achieved with the higher dose seemed to be counterbalanced by a definite increase in gastrointestinal reactions and did not seem to warrant using the higher dose as a routine. In almost all the other groups we found the same situation to hold true, i. e. that the higher dose gave only slightly better results and did not justify the increased incidence of reactions.

Late Benign Syphilis of the Bones, Skin and Mucous Membrane.—Of nine patients with cutaneous syphilis, eight had the nodulo-ulcerative and one the palmar squamous form; of the two with syphilis of the mucous membranes, one had gumma of the palate (congenital,

tardive) and one gumma of the upper lip and nasal septum. The one patient with syphilis of the bones had acute periostitis (congenital tardive).

In six of the eight patients with nodulo-ulcerative cutaneous lesions, the lesions were completely involuted in an average of thirty-one days (range from twenty-two to forty-three). Of the two whose lesions were not healed completely, the lesions of one had healed 60 per cent at the end of fourteen days, at which time treatment was inadvertently discontinued. The other patient at the time of writing had been receiving treatment forty-two days and his lesions were about 80 per cent involuted.

The squamous palmar lesion healed completely in thirty-three days.

The gumma of the palate was a large gumma of the soft palate in a 12 year old girl with congenital syphilis. This lesion healed completely in twenty days. The gumma of the upper lip and nasal septum was in a middle aged man whose syphilis was treatment resistant and relapsing. The lesion did not show any response whatever to bismuth given orally or to arsenicals but finally responded to fever therapy.

The bone lesion was acute periostitis in a child with congenital syphilis. The sobisminol mass was administered in the milk. Complete involution was achieved in forty-two days.

Syphilis of the Central Nervous System.—Sobisminol mass was given to twenty-three patients with neurosyphilis to determine whether this type of bismuth could bring about the relief of symptoms (headache, shooting pains), which we have found consistently with intramuscular administration.

The results obviously depend on the subjective reaction of the patient and therefore are not amenable to exact measurement. However, an effort was made to allow a free expression on the part of the patient, and we did not suggest possible benefits or mention specific symptoms but allowed the patient to volunteer any information he desired.

Of the twenty-three patients, five had such minor complaints that a definite effect could not be determined although in general the results were good. Of the other eighteen almost all had tabetic or meningovascular forms of long duration, all were well complaints and all had symptoms severe enough to enable them to appreciate quantitative changes. Of these eighteen, two felt no effect, fifteen felt better and one felt worse. With four the improvement was temporary, lasting less than two months, and with eleven it was prolonged, having lasted more than two months.

Of those who did get benefit, ten stated that they were almost completely relieved of all symptoms. Most of them gained weight as a result of relief from gastric disturbance and subsequent improved appetite. Five stated that they received "fair" improvement.⁴

TOXICITY AND REACTIONS

Of the ninety patients, seven complained of a bismuth line, ten of stomatitis (three of stomatitis severe enough to warrant interruption of medication), ten of "grip syndrome," thirty of nausea and vomiting, eleven of anorexia, six of diarrhea, one of dermatitis (question-

3. Chambers, S. O., and Scholtz, J. R.: Clinical Application of a Stain for Spirochetes (Krajian), Arch. Dermat. & Syph. 38: 217 (Aug.) 1938.

4. Subsequent experience has definitely confirmed the impression that sobisminol mass taken orally is unusually effective in giving symptomatic relief to patients with late neurosyphilis, particularly of the tabetic type. This effect has been very striking, immediate and lasting even with patients who had previously received large amounts of bismuth intramuscularly without relief. We consider this situation one of the particular indications for oral (sobisminol mass) therapy.

able), none of headache, four of urinary frequency, two of ptialism and parotitis and two of esophageal spasm.

Most of the complications were mild so that of the entire group only four had to discontinue treatment permanently and seven temporarily (for from one to three weeks).

One patient had a peptic ulcer. He has taken six capsules daily for seven months with no difficulty.

Two patients had severe esophageal spasm on one occasion. The pain lasted for several days and was so severe that milk and liquids were almost intolerable. One of these patients had hematemesis for two days, although the amount of blood was very small. The obvious explanation seems to be that the capsules had been held in the lower end of the esophagus long enough to dissolve and cause erosion of the mucous membrane.

Of the entire group of ninety patients forty-seven, or approximately 50 per cent, had one or more reactions. It should be noted, however, that most of these were very mild gastrointestinal symptoms (nausea) which lasted only a few hours or days at the most and did not interfere in any way with the treatment. Their importance can be compared to that of the pain and discomfort of varying degrees which most patients complain of at the time of receiving intramuscular injections but which do not last or interfere with treatment.

RENAL TOLERANCE

Urinary examinations were done for eighty-seven patients (320 specimens).

Four of the patients showed faint traces of albumin in one specimen each. One of these, a 65 year old woman, had been receiving the drug for eighteen months continuously. During this period one specimen showed a 2 plus reaction for albumin, with no other abnormalities. Subsequent examinations over a period of six months gave no further positive results.

One patient showed persistent traces of albumin for several months and granular casts on one occasion. This patient, however, had shown traces of albumin for several months before beginning oral bismuth therapy.

The other two patients each showed a 1 plus reaction for albumin on one occasion. No other abnormalities in the urine were noted. Subsequent urinary examinations on continuation of treatment gave normal results.

All the patients in this group took adequate doses of the drug during the entire period of observation.

PROLONGED THERAPY

Thirty-eight patients received the drug for two months or more without interruption. Of these, nine were unable to tolerate more than four capsules (0.56 Gm. of bismuth) daily. More than four capsules caused troublesome gastrointestinal reactions.

Five patients have been taking the drug daily for more than a year with no complaints: seven for two months, twelve for three months, four for four months, five for five months, two for six months, one for seven months, two for eight months, two for twelve months, two for fourteen months and one for eighteen months.

The incidence of reactions in this group was similar to that in the general group, i. e. most reactions occurred in the first few days or weeks and thereafter became less frequent, so that most patients had no difficulties whatever after the first two months.

The important feature therefore is that there seems to be no tendency to cumulative toxic effects. Further observation may prove otherwise.

EVIDENCE OF SUSTAINED THERAPEUTIC EFFECT

In general it can be stated that, so long as daily treatment is continued, the therapeutic effect seems to be sustained. None of our patients had relapse or progression while under treatment except the patient with gumma of the lip, who was treatment resistant from the outset.

On the other hand, from the clinical standpoint we have found certain evidence which suggests that the effect in many instances disappears rather rapidly after treatment is discontinued. In two cases of secondary syphilis, oral treatment with bismuth was carried to complete involution of the lesion (about two weeks), at which time the patients were to be given arsenical therapy. Because of nonattendance of the patients, arsenical therapy was not immediately begun and both showed reactivation of the lesions within two or three weeks.

It has also been observed that in several of our cases of symptomatic neurosyphilis the relief from symptoms is lost within a few weeks after therapy is discontinued, suggesting that a certain level of bismuth in the blood must be maintained for good results and that this level drops rapidly soon after discontinuance of oral medication.

These observations, although far from conclusive, raise an important question which should be investigated. Studies of urinary excretion in human beings will supply a partial answer, and we hope to report soon on such studies.

Sollmann and Cole⁵ in recent studies have reported that, "when the administration was stopped, the urinary excretion dropped promptly." Our yet unpublished excretion studies indicate the same conclusion.

COMMENT ON CLINICAL RESULTS

The results reported allow the following statements:

1. Sobisminol mass administered (daily) in doses containing about 0.84 Gm. of bismuth is absorbed from the gastrointestinal tract in a therapeutically active form in sufficient quantities to bring about involution of active syphilitic lesions of the skin. Involution is achieved in periods comparing favorably with those when preparations for intramuscular administration are used. The time required in cases of primary and secondary syphilis is only slightly greater than when neoarsphenamine is used.

2. Sobisminol mass (orally) in daily doses containing about 0.84 Gm. of bismuth brings relief from the symptoms of late neurosyphilis (particularly tabetic) in a high percentage of cases and appears to offer a definite advantage over any drug heretofore used.

3. Sobisminol mass (orally) is well tolerated by most patients. There is a high incidence of mild gastrointestinal reactions which rarely interfere with treatment. There are no reactions which compare in gravity to the embolism (arterial and venous) and abscess which occur with intramuscular injection with sufficient frequency to make them considerations for concern.

4. Sobisminol mass can be administered every day for many months without producing cumulative toxic effects.

5. Our material does not allow us to say that sobisminol mass (orally) can be substituted for other forms

5. Sollmann, Torald; Cole, Harold, and Henderson, Katharine: Clinical Excretion of Bismuth: V. Excretion of Sobisminol and of Some Other Bismuth Preparations for Oral Administration, Arch. Dermat. & Syph. 37: 993 (June) 1938.

of bismuth in the routine treatment of early syphilis. All circumstantial evidence points to the fact that sobisminol mass (orally) will do whatever any other bismuth preparation will do, but the ultimate proof lies in a treated series observed for several years.

6. Oral therapy has the disadvantage that its efficiency depends on the intelligence and honesty of the patient (patients are frequently lax and dishonest to their own disadvantage).

7. If oral bismuth therapy receives approval, great care must be exercised in the control of its distribution. Self medication of syphilis is worse than no medication.

CONTROL OF PROTHROMBIN DEFICIENCY IN OBSTRUCTIVE JAUNDICE

BY USE OF VITAMIN K

J. D. STEWART, M.D.

AND

G. M. ROURKE, B.A.

BOSTON

Abundant experimental and clinical evidence obtained in the past four years shows that a fat-soluble substance, called by Dam vitamin K,¹ conditions the formation of prothrombin by the liver.² In obstructive jaundice at least two factors tending to depress plasma prothrombin are at work, one being damage to the liver and disturbance in its synthetic function and the other the diminished absorption of vitamin K from the intestinal tract. Bile salts have been shown to be necessary for the absorption of fat-soluble substances from the intestinal canal,³ and in obstructive jaundice the bile delivered into the duodenum may be deficient in bile salts as well as in total volume. Another factor of importance in lowering plasma prothrombin in patients with obstructive jaundice is loss of appetite with inadequate intake of foods containing vitamin K.

The data presented in this report were obtained in the management of cases of obstructive jaundice at the Massachusetts General Hospital during the past twelve months.

METHODS

Plasma prothrombin was determined by the method of Warner, Brinkhous and Smith, with modifications as previously described.⁴ The values are expressed in percentage of normal. Fibrinogen was determined in duplicate on the oxalated plasma by the method of Cullen and Van Slyke, the clot obtained from 1 cc. of plasma being subjected to microdigestion and nesslerization. Plasma bilirubin was measured as follows: Two

cc. of plasma was combined with 1 cc. of diazo reagent and allowed to stand ten minutes. Then 2 cc. of saturated ammonium sulfate and 10 cc. of 95 per cent alcohol were added. The mixture was centrifuged, and the color of the supernatant fluid was read against the cobaltous sulfate standard prepared according to McNee and Keefer.⁵ Ascorbic acid was determined in the samples of fasting plasma according to Pijoan and Klemperer.⁶ The bromsulphalein test was made in the usual way, a calibrated syringe being used to inject a measured quantity of the dye per pound and the concentration in the serum thirty minutes later being read colorimetrically against stock standards. The hippuric acid test was performed as described by Quick.⁷ A urea clearance determination was made during the same four hour period, urea in blood and urine being measured by the gasometric method of Van Slyke.⁸

Determinations of plasma prothrombin, bilirubin and fibrinogen were made repeatedly before and after operation.

The vitamin K extract used in this work was prepared from fresh spinach according to the method of Dam, as previously described.¹ One gram of the vitamin K-cholic acid mixture contained 0.45 Gm. of sodium glycocholate (Merck), 0.45 Gm. of sodium taurocholate (Merck), and 0.1 Gm. of extract derived from 200 Gm. of fresh spinach. In several instances a commercial preparation of vitamin K was used, as noted in the tables.

RESULTS

therapy, the postoperative drop and the secondary response are well shown. There was no abnormal bleeding in this case, as the prothrombin level was kept well above the hemorrhagic zone. Fibrinogen and prothrombin values appear to be unrelated.

The data shown in chart 2 were obtained in the study of a 73 year old patient with carcinoma of the papilla of Vater. The prothrombin value was initially at the dangerously low level of 23 per cent but responded

acid given by jejunostomy. There was no abnormal bleeding, and the patient made an uneventful convalescence.

In chart 3 are seen the effects of a bout of cholangitis on prothrombin response to vitamin K-cholic acid therapy. When first studied, the patient's jaundice was of only three days' duration and the prothrombin was only slightly reduced. The subsequent retardation of response to vitamin K therapy illustrates the importance of the condition of the liver, for even though adequate amounts of vitamin K-cholic acid mixture

concentration fell even under vitamin K-cholic acid therapy.

In table 1 are shown prothrombin data at the time of massive pathologic bleeding in obstructive jaundice. The danger zone is seen to be below 40 per cent. The patients had either had no vitamin K-cholic acid mixture or else had had insufficient quantities. Proper vitamin K-cholic acid therapy resulted in rapid cessation of bleeding and elevation of prothrombin in all except three cases. The condition of R. G. and M. L. K. was hopeless, and specific therapy and study were

unjustifiable. Patient T. P. H. had severe liver failure with ascites, anuria, peripheral edema and delirium, and liver function was probably too greatly reduced to make a prothrombin response. Nevertheless, in the last-mentioned case the question is complicated by possible failure of the patient to absorb the mixture fed by jejunostomy on account of brisk diarrhea.

Chart 2 (E. W.).—Plasma prothrombin changes in response to administration of vitamin K-cholic acid mixture, 1.2 Gm. a day, given orally before operation and by jejunostomy after operation. This was a case of carcinoma of the papilla of Vater and cholecystoduodenostomy. *P* indicates plasma prothrombin concentration in percentage, *F* indicates fibrinogen in grams, *Vc* indicates cell volume in percentage and *B* indicates plasma bilirubin in milligrams per hundred cubic centimeters. No pathologic bleeding occurred.

In tables 2 and 3 are shown preoperative data in fifteen cases of obstructive jaundice due to stone and in nine cases due to carcinoma. The data obtained in the liver function tests are of interest in connection with the initial prothrombin response to treatment. Hard and fast conclusions are not to be drawn in such a study, but in general as compared with the patients having obstruction due to stone the patients with carcinoma were jaundiced longer, showed poorer liver and renal function, were more deeply jaundiced and had lower plasma ascorbic acid values and higher fibrinogen values. The plasma prothrombin concentration before and after treatment was definitely lower in the patients with carcinoma. In none of these cases was there failure to establish a safe prothrombin concentration as the result of preoperative treatment. In both groups the plasma ascorbic acid concentration was subnormal, which is indicative of the malnutrition so common in obstructive jaundice.

COMMENT

The uniformity with which prothrombin deficiency is found in obstructive jaundice is striking. In general terms the longer the duration of the jaundice and the greater the liver damage, the lower the plasma prothrombin concentration. Nevertheless, even as early as three or four days after the onset of biliary obstruction there may be moderate reduction in the prothrombin level, so labile is this factor. There is, on the whole, agreement between clinical appraisal of the patient's condition, the results of liver function tests and the extent of prothrombin deficiency. Further study may indicate that the prothrombin depression is a better index of liver damage than other standard liver function tests.

A question of much interest is the possibility of increasing the prothrombin value to an abnormally high level by heavy vitamin K-cholic acid feeding, with

resultant pathologic increase in clotting tendency. In none of the jaundiced patients thus far studied have abnormally high prothrombin values been observed after treatment. There seems to be a rather definite tendency for the prothrombin value to be stabilized close to normal under treatment. The question has been investigated further in a group of patients not suffering from liver disease and having normal prothrombin values. In three such patients from 1.2 to 2.4 Gm. of vitamin K-cholic acid mixture was fed daily for from six to twelve days with no significant change in prothrombin concentration. Since this is two or three times the quantity necessary to restore the level to normal in obstructive jaundice, there evidently exists a considerable margin of safety in administering the mixture.

Reduction in prothrombin of from 20 to 30 per cent is usually seen immediately after operation, probably dependent on such factors as blood loss, anoxemia, effect of anesthetic agent and cessation of intake of vitamin K. In our cases the postoperative drop occurred within the first four days. Since the prothrombin value is so labile, the importance of giving vitamin K with little delay after operation is apparent. For this reason in several instances we have performed jejunostomy at the time of operation on the biliary tract and have continued giving the vitamin without intermission. Occasionally jejunostomy is justifiable for this purpose in preparing a patient for operation, though nasal tube feeding should be tried first if the patient seems unable to take the mixture.

A question of practical importance is How necessary are frequent determinations of plasma prothrombin

Chart 3 (J. M. S.).—Effect of cholangitis on vitamin K response in obstructive jaundice due to stone in the common duct. Vitamin K-cholic acid mixture, 1.2 Gm. a day, was given orally. *T* indicates oral temperature, *P* indicates prothrombin concentration in percentage, *F* indicates fibrinogen in grams per hundred cubic centimeters, and *B* indicates plasma bilirubin in milligrams per hundred cubic centimeters.

in treating obstructive jaundice with vitamin K-cholic acid mixture? Admittedly the determination is rather tedious and complicated and requires careful attention to details. Eventually knowledge of the subject may be sufficiently satisfactory to warrant routine administration of vitamin K-cholic acid mixture. However,

study of prothrombin concentration is highly desirable until such matters have been settled as the toxicity of vitamin K and cholic acid in obstructive jaundice, the possibility of hyperprothrombinemia, the incidence of refractory hypoprothrombinemia, the purification of vitamin K and the standardization of dosage.

Since the extent of reduction in prothrombin in obstructive jaundice and the ability to respond to vitamin K-cholic acid therapy depend on the degree of depression of liver function, an essential part of the treatment consists of measures known to aid liver function. The patient should receive from 400 to 600 Gm. of carbohydrate daily, by mouth or by vein. Proper amounts of water and sodium chloride must be taken daily, for derangement of liver and renal function makes fluid therapy particularly important. Early decompression of the obstructed biliary tract reduces the damage to the liver cells, and for this reason a two stage operation is often desirable for the sicker patients with neoplastic obstruction to the common duct. In such cases drainage of the gallbladder with local anesthesia after two to four days of preparation may be followed by a safer anastomosis of the gallbladder to the gastrointestinal tract two weeks later.

CONCLUSIONS

1. Prothrombin deficiency in obstructive jaundice depends on such factors as duration and degree of biliary obstruction, infection, avitaminosis K and malnutrition.

2. Response to administration of vitamin K-cholic acid mixture is immediate except with rapidly progressing liver damage.

3. Massive pathologic bleeding may occur with prothrombin values below 40 per cent.

4. Hyperprothrombinemia during vitamin K-cholic acid therapy was not observed during this study.

5. Important also in treating prothrombin deficiency in obstructive jaundice are administration of dextrose and proper fluids and early decompression of the biliary tract.

ABSTRACT OF DISCUSSION

DR. H. P. SMITH, Iowa City: As the authors have stated, patients are definitely in danger of bleeding when the plasma prothrombin level is less than 40 per cent of normal. I think they will agree that vitamin K should be given even when the prothrombin level is as high as 70 per cent. One thereby prevents the patient from falling into the danger zone later on. It is of interest that some patients bleed at the 30 per cent level, whereas others do not. I find that in some cases thrombin develops in clotting blood more rapidly than in others. This is a compensation which to some extent corrects for a deficiency in the amount of prothrombin. It is of interest that in the dog this compensatory mechanism is highly developed, and dogs do not bleed until the prothrombin reaches the astonishingly low level of 10-15 per cent. In man, as the authors pointed out, bleeding commonly begins at the 40 per cent level, but this varies with the degree of compensation present. The fall in the prothrombin level with liver injury is important. This supplements animal experiments which showed a fall in plasma prothrombin when the liver is partially removed or when it is injured by chloroform or phosphorus. It is evident that the liver is a factory concerned in the manufacture of prothrombin. Vitamin K is one of the raw products used by the liver, and without vitamin K the liver cannot perform this important duty. A lowering of the plasma prothrombin level may therefore be due either to shutting off the supply of raw material (vitamin K) or to an injury to the factory—the liver. The feeding of vitamin K corrects the former but not the latter. The suggestion that the prothrombin level be used as a test of liver function is of merit. It must be remembered that the manufacture of prothrombin is merely one of the duties of the liver. It is

possible that some types of liver injury depress certain liver functions more than others, and the prothrombin test may not indicate the degree to which certain other functions are depressed. But with this qualification the test should be a valuable addition to the liver function tests already available.

DR. HUGH R. BUTT, Rochester, Minn.: I should like to compliment the authors on their presentation and to ask two questions: First, how long did they allow the concentrates of vitamin K to be mixed with cholic acids before being administered? Second, how long after the administration of vitamin K was the so-called immediate response noticed? The treatment of hemorrhage in patients with jaundice often presents a very difficult problem. For those individuals who have a very low level of prothrombin in the blood it has been the custom to administer rather large doses of concentrates of vitamin K and bile salts through a duodenal tube. In such instances it is perhaps best to mix 1 or 2 Gm. of animal bile salts in 400 or 500 cc. of warm physiologic solution of sodium chloride and add to this 1 or 2 cc. of the crude concentrates. This is mixed well and administered slowly. For some patients it is necessary to repeat this procedure one or more times in order to reduce the clotting time to near normal. The problem of treating patients who are actively bleeding is extremely difficult. Clotted blood often must be removed from the stomach and occasionally the biliary tract must be irrigated before proper absorption of the administered materials can take place. During the past two years my associates and I have encountered a group of patients who had very little jaundice and whose prothrombin levels before and after operation were normal but who nevertheless bled occasionally postoperatively. These patients have been found among the group suffering with acute, subacute and chronic cholecystitis with stones. A few of these patients have had massive hemorrhages, and bleeding in most instances has been controlled by the adequate administration of vitamin K and bile salts. This group of patients emphasizes again the importance of the normal integrity of the liver in the management of hemorrhagic diathesis of patients with jaundice. In other words, jaundice does not necessarily accompany cholemic bleeding in all patients with hepatic injury and, finally, a normal level of prothrombin at the time of operation or after operation does not guarantee against the recurrence of cholemic bleeding at a later date.

DR. L. WALLACE FRANK, Louisville, Ky.: I wish to call attention to the use of vitamin K in the treatment of hemorrhage from the upper gastrointestinal tract. It is not uncommon to see profuse bleeding from this region which is not associated with ulcers and not associated with tumors but is associated with hypertrophic gastritis and duodenitis. In a small series of cases observed since November of last year the blood prothrombin according to the Quick method was estimated at from 65 to 70 per cent of normal when the bleeding began. One of these patients has been observed over a period of five months. He has bled on two occasions and at each time the blood prothrombin was 65 per cent of normal. What initiates bleeding from the upper gastrointestinal tract in this type of case, i. e. hypertrophic duodenitis, is satisfactorily explained by Dr. H. E. Robertson, of the Mayo Clinic. He has demonstrated rather conclusively in such cases that erosion of the mucosa occurs which extends into a more or less rich vascular network in the submucosa. The amount of blood loss varies in relation to the size of the vessels. It is my belief that if the individual's blood prothrombin is high or normal the blood loss will be negligible but if the prothrombin is low the hemorrhage may become alarming. I have used vitamin K in the treatment of such hemorrhage with success.

DR. JOHN D. STEWART, Boston: I am grateful to the discussers for their authoritative comments on this subject. Dr. Butt raised two or three interesting questions. With regard to whether one can say that vitamin K stimulates the formation of prothrombin, this is a difficult question since the exact relationship between vitamin K and prothrombin is not known. It is probably wise to say that vitamin K conditions the formation of prothrombin by the liver in a manner as yet undetermined but with definite quantitative implications. Another question was How long was the mixture of vitamin K and bile salts kept before using in our study? We have used for a period of nine months the same preparation. This has been stored in an ice box at minus 35 C. and has been carefully protected

from sunlight. There has been no recognizable diminution in potency of the mixture during this nine months period, as shown by prothrombin response in patients. Concerning the matter of rapidity of response, the patient's prothrombin concentration was 9.8 per cent at the time of massive bleeding. Twelve hours later, under vitamin K therapy, the prothrombin concentration was 40 per cent. This shows how quickly the remedial effect of vitamin K occurs, provided the substance is absorbed properly from the gastrointestinal tract. An important point is the method of administering the mixture of vitamin K and bile salts. Dr. Butt stated that it may be given through a nasal tube into the duodenum. We have used this technic with satisfaction. Nevertheless there is great need for a pure and effective preparation of vitamin K which can be given parenterally, perhaps eliminating the necessity of the patient's taking bile salts. Progress in this direction is being made. With regard to the reduction in prothrombin in other conditions besides obstructive jaundice of which Dr. Frank spoke, we have encountered such reduction in cases of ulcerative colitis, chronic sepsis and peptic ulcer. We have used vitamin K in treating such cases with apparent success. Dr. Butt tells me that he has recently studied a group of cases with reduction in prothrombin dependent perhaps on a general loss of intestinal mucosal absorptive power, and in such cases there was response to oral administration of vitamin K mixture.

PRESERVATION OF STORED BLOOD WITH SULFANILAMIDE

MILAN NOVAK, PH.D., M.D.
MINNEAPOLIS

Blood transfusion in recent years has become an increasingly important and simplified procedure in most well organized hospitals. The establishment of blood banks and the storing of blood have facilitated the use of this valuable therapeutic agent. The usual technic employed in the United States is that of the Cook County Hospital,¹ consisting of the addition of 0.35 Gm. of chemically pure sodium citrate in physiologic solution of sodium chloride to each hundred cubic centimeters of blood. This gives an adequate amount of sodium citrate for the prevention of coagulation, and after sterility and typing tests and serologic tests for syphilis the blood is available for transfusion for about ten days or more. Standardized serologic tests for typing and for the detection of syphilis give satisfactory results when carefully done. However, sterility tests on stored blood not only are technically hazardous to carry out but also give results difficult to interpret, especially when cultures yield negative results. The importance of determining sterility is usually not seriously considered. None of the reports from different hospitals describe any systematic examination for bacterial contamination after the blood has been stored. Several such articles state that up to 50 per cent of the stored blood is contaminated with bacteria but that its use is not contraindicated. The lack of serious consideration for methods of determining sterility is evidenced in the following statement by Page, Scager and Ward:² "Fifty specimens of blood after having been stored for varying periods showed no obvious contamination as evidenced by discoloration of the blood or froth on the surface." The frequency of transfusion reactions, which ranges up to 50 per cent, depending on the index used for defining a transfusion

reaction, gives evidence that there may be other factors than those usually considered to be responsible. The utter disregard for bacteria and their by-products in relation to transfusion reactions seems unjustified in the light of knowledge as to the toxic and pyrogenic reactions which they produce within the host. The recent work of Co-Tui and his associates³ on the production of pyrogens by nonpathogenic bacteria in solutions before intravenous use with resultant adverse reactions in patients receiving such products serves again to emphasize the necessity for exercising the utmost care in the prevention of gross contamination in solutions to be administered intravenously.

As to its source, contamination is most likely to occur when the blood is drawn from the donor. Assuming that all glassware, instruments and solutions used are sterile, there still remain several sources from which the blood can become contaminated. Complete sterilization of the skin previous to phlebotomy is impossible, since there are always a few bacteria which escape the bactericidal action of any cutaneous antiseptic.⁴ The needle in its course through the skin may encounter these viable organisms, and the chance for introducing them into the bottle with the blood is high. The addition of the anticoagulant solution to the bottles at the time of drawing the blood from the donor is another possible source of bacterial contamination. Manipulation of the needle in attempts at venipuncture, especially in difficult subjects with small veins, increases the possibility for the inadvertent introduction of a chance contaminant. The likelihood of the presence of a transient asymptomatic or an unrecognized bacteremia in the donor subjects the recipient of such blood to the

the question of sterility, since the postmortem invasion of the blood stream by bacteria is extremely rapid. In the collection of placental blood⁶ the chance for bacterial contamination is far from remote. Hence the possibilities for bacterial contamination are not denied, yet the seriousness of the use of grossly contaminated blood has not been sufficiently emphasized.

The detection of contamination in stored blood is an uncertain procedure, since the number of organisms is usually small. The culturing of 1 cc. of blood from a 500 cc. quantity, as is done as a matter of routine at the time the blood is drawn from the donor, will certainly give questionable results, since a report of sterility may mean merely that the few organisms in the original bottle were not transferred in the portion cultured. The sampling error in the accepted procedure is therefore exceptionally great. On the other hand, the periodic removal of samples for culturing purposes during the period of storage is even more hazardous, since contaminants may be introduced into the flask of blood by this procedure, and hence it cannot be recommended as a routine.

plication of the different strains of organisms involved in contaminated stored blood was sulfanilamide in 1:1,000 concentration. The purpose of the present work is to determine the least amount of the drug needed to produce bacteriostasis for the various periods during which blood is usually stored. The determination of the smallest amount necessary is important, especially when large quantities of the drug are contraindicated or when multiple transfusions are to be given.

METHOD

The procedure consisted of inoculating 10 cc. of freshly drawn citrated (0.3 per cent) human blood with twenty-four hour cultures of strains of bacteria previously isolated from contaminated stored blood. An attempt was made to introduce less than 3 bacteria per cubic millimeter of blood. Various amounts of sulfanilamide were added to produce final concentrations ranging from 2.5 to 100 mg. per hundred cubic centimeters of blood, except for a control tube which contained no sulfanilamide. After thorough mixing, 0.1 cc. quantities were removed from each sample, added

Following the finding of a considerable amount of contamination in stored blood samples, it became obvious that the problem was being neglected. About 5 per cent of blood which had been stored for ten days was found to be grossly contaminated. The organisms found most frequently were aerobic or anaerobic spore-forming rods and staphylococci, both aureus and albus species. Occasionally *Pseudomonas aeruginosa* was found, and on one occasion a beta hemolytic streptococcus was isolated. Since blood is an excellent medium for bacteria, growth of these organisms takes place in blood even at 4 to 6 C., the temperature at which blood is usually stored. Quantitative bacteriologic determinations disclosed the fact that contaminated stored blood contained as many as 2,000,000 organisms per cubic centimeter.

The possibility of using a bacteriostatic substance in doses compatible with intravenous administration was suggested by one of us⁷ in a previous paper. Of the several substances investigated, the only one which completely inhibited for as long as six weeks the multi-

to a tube of molten agar and poured on a Petri plate. This was repeated at regular intervals, during which time the samples remained in a refrigerator at 4 to 6 C. Colonies were counted after a forty-eight hour period of incubation. The results shown in the tables were obtained with the organisms most frequently isolated from contaminated stored blood.

These results indicate that for a period of fifteen days a concentration of 20 mg. or less per hundred cubic centimeters is adequate but that for a longer period even 100 mg. is not sufficient in case the contaminant is *Pseudomonas aeruginosa*. However, since this is a relatively infrequent contaminant and since blood is not often stored for such long periods, the smaller quantities of the drug would usually be sufficient. Table 2 shows results with lesser concentrations of the drug.

The data indicate that a concentration of 20 mg. per hundred cubic centimeters of sulfanilamide is adequate if blood is to be stored up to ten days or two weeks. On transfusion of 500 cc. of blood containing this proportion of sulfanilamide, the amount of the drug introduced would be about 1½ grains (0.1 Gm.), which is an extremely small dose. Since the drug is readily absorbed from the blood by the tissues and since it

6. Goodall, J. R.; Anderson, F. O.; Altman, G. T., and McPhail, F. L.: Inexhaustible Source of Blood for Transfusion and Its Preservation, Surg., Gynec. & Obst. 66: 176-178 (Feb.) 1938.

7. Novak, Milan: Use of Bacteriostatic Drugs in Preservation of Blood for Transfusion, Proc. Soc. Exper. Biol. & Med. 42: 210-211 (May) 1939.

is likewise rapidly excreted, it is doubtful that any detectable elevation of blood sulfanilamide level will result even when multiple transfusions are administered. Since there is progressive deterioration in the various elements of blood, as pointed out recently by Kolmer,⁸ and since the control of bacterial multiplication is uncertain, even with sulfanilamide added, in blood stored for longer periods, it does not seem advisable to store blood for more than ten or fifteen days.

The possibility of using sulfanilamide in the preservation of other biologic products is worthy of consideration, since the drug does not tend to precipitate proteins, as frequently happens when other preservatives are used.

SUMMARY

1. Contamination of stored blood with bacteria has not been considered seriously enough in the past.

2. Many unexplained transfusion reactions may be due to pyrogens or other bacterial by-products in contaminated blood.

3. Complete bacteriostasis of the usual bacterial contaminants in stored blood is made possible by the addition of 20 mg. per hundred cubic centimeters of sulfanilamide. Such blood will not only not support bacterial growth for ten to fifteen days but may actually become sterile in that time.

4. Sulfanilamide may prove valuable as a preservative in other biologic substances.

Clinical Notes, Suggestions and New Instruments

ACETANILID POISONING

ALAN LESLIE, M.D., NEW YORK

Acetanilid poisoning presents a clinical picture which is of importance because of the incorporation of the drug in popular, widely advertised headache remedies. Cases of poisoning were reported as far back as 1886 by Eisenhardt¹ and 1890 by Herrmann.² The number of such reports varied with the current popularity of preparations containing the drug. In the early years of the present century Stewart,³ Herrick and Irons⁴ and others cited many instances of poisoning.

Two types of poisoning from acetanilid may occur. The acute form may be seen after ingestion of a normal therapeutic dose (0.2 Gm.) if there is an idiosyncrasy, as has been reported by Lundsteen, Meulengracht and Rischel,⁵ or after ingestion of the drug in dosage ordinarily regarded as toxic. However, as much as 4 Gm. has been taken at one time with no apparent ill effect. Acute acetanilid poisoning is characterized mainly by cyanosis, chills, exanthems, abdominal distress with vomiting, diffuse neurologic disorders, coma, circulatory collapse and occasionally death from cardiac failure. In cases of chronic poisoning, in addition to any of the manifestations already mentioned, there are commonly anorexia, so-called aniline cachexia, asthenia and secondary anemia. Herrick and Irons⁴ called attention to the splenomegaly which occasionally occurs. Cases combining features of both acute and chronic poisoning are frequent.

REPORT OF CASE

History.—C. A., a white man aged 46, a soda fountain attendant, had for many years had severe right frontoparietal headache suggestive of migraine; this had been markedly worse during the two months before admission to the Mount Sinai Hospital. A right intranasal antrotomy four years before admission did not relieve the headache. "Bromo Seltzer," taken on an average of five times a day, was fairly efficacious in relieving the headache prior to the two months of aggravated symptoms, during which time from fifteen to twenty standard soda fountain doses were taken every day with little if any effect (each dose contains approximately 0.24 Gm.). Four days before admission the patient complained of malaise and anorexia. The temperature was 103 F. and there was mental clouding. There were two episodes of vomiting. The temperature dropped to normal during the next three days, but the mental aberration became worse. No medication was taken during this time. On admission the patient was disoriented and stuporous.

Examination.—The patient was semicomatose, pale and thin, with a striking dusky, grayish cyanosis, especially of the lips and finger nail beds, which were violaceous. The heart sounds were of fair quality. A few crepitant rales were heard at the left base. The pulse was thready. Abdominal examination was negative and there was no adenopathy. The blood pressure was 108 systolic and 74 diastolic.

Neurologic examination revealed that the pupils were equal and reacted sluggishly to light and in accommodation. There was bilateral nystagmus. There was intention tremor with asthenia and asynergia. The deep reflexes were hyperactive, more on the right than on the left side. The right cremasteric reflex was diminished and there was a bilateral Oppenheim reflex. The Babinski sign was absent.

Laboratory Data: The hemoglobin content was 84 per cent (Sahli). The white blood cell count was 7,800. The differential count showed 77 polymorphonuclear leukocytes, of which 16 were nonsegmented cells, 14 lymphocytes, 8 monocytes and 1 eosinophil. The urine was a dark reddish brown and had a yellowish foam. A trace of bile was found, and urobilin was present in concentration of 1:60. The icteric index was 3 and the blood urea nitrogen was 14 mg. per hundred cubic centimeters. The Wassermann reaction of the blood was negative. Lumbar puncture showed clear fluid under pressure of 120 mm. of water, with no block. Reaction to the Pandy test was negative. Microscopic examination showed 3 lymphocytes. The Wassermann test on the spinal fluid and the colloidal gold test gave negative results. Spectroscopic examination of the blood failed to show the absorption band for methemoglobin or sulfhemoglobin. Although the urine remained dark for five days, bile was reported absent from the later specimens. The indophenol reaction for para-aminophenol was equivocal. X-ray examination of the chest showed no abnormality.

Course.—There was rapid improvement with administration of abundant fluids. The psyche was completely clear after a week of hospitalization. The abnormal neurologic signs disappeared, although the tremor of the hands persisted. The handwriting, which was a scrawl shortly after admission, became legible. A second white blood cell count was 18,000 with 80 per cent polymorphonuclear leukocytes and 20 per cent lymphocytes; hemoglobin was 90 per cent (Sahli) and the red blood cell count was 5,000,000. The temperature, which was 100.6 F. on admission, became normal on the third day and remained so until discharge ten days later. The headaches were immediately and entirely relieved by withdrawal of the drug. However, they recurred, but only infrequently (about once a month), lasting from twelve to twenty-four hours, after the patient was discharged. They were unaffected by the intramuscular administration of ergotamine tartrate but have been relieved by acetylsalicylic acid (0.6 Gm.).

COMMENT

Cyanosis, the most frequent presenting sign in acetanilid poisoning, may be present in varying degrees. It is not due to oxygen unsaturation but to the presence of the dark colored

oxidation products of para-aminophenol,⁶ and perhaps to the presence of methemoglobin or sulfhemoglobin.

Tolerance to the drug is built up after continued use. For occasional use, for headache or lassitude, acetanilid is a powerful analgesic preparation of great value. However, if it is abused there is actually a tendency toward production of headache with the resulting establishment of a vicious circle. Presumably this was true in the case described, since withdrawal of the drug resulted in practically complete disappearance of the headache. If the drug is stopped abruptly after a long period of use there may be withdrawal symptoms of variable severity.

The treatment of acetanilid poisoning is not difficult unless symptoms of withdrawal are marked. Ordinarily, forcing of fluids by all available routes is sufficient. If the patient suffers from lack of the drug, withdrawal symptoms can be alleviated by the administration of small doses. Smith⁷ found that the addition of sodium bicarbonate to acetanilid in a molecular ratio of 1:2 reduces the mortality of experimental rats, so this drug might be used to therapeutic advantage. Collapse should be treated as is collapse from any other cause. Symptomatic treatment adds to the patient's comfort. Most of the symptoms disappear after elimination of the drug, although neurologic manifestations occasionally persist.

111 East Seventy-Fifth Street.

SPOOL COTTON AS A SUTURE MATERIAL

WILLIAM H. MEADE, M.D., AND ALTON OCHSNER, M.D.
NEW ORLEANS

Whereas there has been a noticeable trend toward the use of nonabsorbable suture materials, particularly silk, in the past five years, undoubtedly the average physician fears nonabsorbable sutures because pathologists and some of the older surgeons have emphasized that "foreign bodies" are detrimental to tissues. This fear has deterred him from using nonabsorbable suture materials and has been justified by the poor results obtained from their incorrect use.

As Guerry¹ and Gage² have used successfully fine spool cotton as ligatures for many years, it occurred to us that the same material in proper sizes might also be used throughout major operations. Susruta about 500 B. C.³ recommended

Chart 1.—Grade of cellular reaction of various suture materials.

cotton for the suture of wounds of joints and the abdomen and recently Ginkovskiy,⁴ after considerable experimental animal work, advocated the use of cotton in surgical procedures on man.

In a previous paper we⁵ showed the comparative reactions of tissue (rabbit) to catgut, silk, linen and cotton sutures (chart 1). The last produced less cellular exudation and earlier healing than any of the others. Whereas dry cotton has less tensile strength size for size than catgut, silk or linen after being placed in tissues, it showed much less decrease in tensile strength (break strength) than the others (chart 2). Halsted⁶

Chart 2.—Alteration in tensile strength of suture materials placed in tissues as compared with the tensile strength of the respective sutures before tissue implantation. The suture material was sterilized and then a portion of it was used for determining tensile strength. This tensile strength was taken as 100 per cent. The remaining sterile portion of the suture material was embedded in tissue for varying periods, from two days up to eighteen, at which time the tensile strength was determined and the percentage decrease in the tensile strength calculated. As shown, there was no change in the tensile strength of cotton until after the tenth day, whereas with the other materials there was a progressive decrease in tensile strength in material which had been placed in tissue.

and Howes and Harvey⁷ showed that there was no need for using a suture which had greater tensile strength than the tissue in which it was placed. Unquestionably there is a tendency for many surgeons to strangle and mutilate tissue when handling sutures of great strength.

Catgut and the materials used in its preparation for use as a suture, chromic acid salts, tannates, iodine, copper and solution of formaldehyde are all deterrents of "dry" wound healing. These chemicals, in addition to the animal protein, produce an inflammatory reaction characterized by an increased exudation which Gage² has termed "wet" type of healing, whereas cotton and silk produce little inflammatory reaction, thus resulting in a "dry" type of healing which is associated with early fibroblastic proliferation.

Ordinary and mercerized spool cotton thread is made from long fiber sea-island and Egyptian cotton. The ordinary spool cotton is made up of six twisted cords and the mercerized of three. In contrast to silk, which is a keratin-like protein, cotton is cellulose. Our investigations⁵ showed that there was practically no tissue ingrowth in cotton sutures in contrast to silk, in which each fibril is separated from the other by fibrous tissue. The lack of tissue ingrowth can be explained by the compactness of the cotton thread, which is due to the natural twist of fibril. We believe that the ingrowth of granulation tissue into the silk suture is responsible for the development of the occasional silk sinus, and for the same reason cotton will not produce sinuses because infected tissue cannot invade the suture.

A bacteriologic examination of unsterilized cotton thread showed, besides the ordinary pyogenic organisms, an anaerobic one which resembled *Bacillus histolyticus* in its cultural characteristics. *B. welchii* and related gas organisms and *B. tetani* could not be demonstrated in eighty different samples. All contaminants were killed by boiling for twenty minutes or by autoclaving for fifteen minutes at 15 pounds pressure (cultured

aerobically and anaerobically in beef broth bouillon and litmus milk for fifteen days).

When boiled for twenty minutes, cotton thread increases 10 per cent in tensile strength, whereas silk changes but little (chart 2). When placed in tissue it loses 10 per cent of its tensile strength in fourteen days, whereas catgut loses from 50 to 70 per cent and silk 35 per cent. Owing to cotton's greater coefficient of friction, a square knot holds better than it does in silk or catgut, making it possible to cut the suture closer to the knot. However, when mercerized cotton is used to coaptate tissue under tension a triple throw knot should be tied and then the suture cut on the knot.⁸

In the use of cotton as with silk, we follow strictly the tenets of Halsted,⁹ which were (1) to use interrupted sutures only, (2) never to use coarse suture material, (3) never to bridge over a dead space as a chord substitutes an arc, (4) to use transfixion sutures in ligation, as finer material could be used in this way, (5) to use a greater number of fine stitches rather than a few coarse ones and (6) to avoid the combined use of buried absorbable and nonabsorbable sutures. If these rules are disregarded trouble is likely to follow, as we have unfortunately experienced.

Spool cotton thread, plain and mercerized, has been used throughout 196 operations, among which were thyroidectomies, radical and simple mastectomies, herniorrhaphies, intestinal obstructions, perforated peptic ulcers, cholecystectomies, appendectomies, colostomies, thoracoplasties, tenorrhaphies, splenectomies, gastro-enterostomy, pneumonectomy and ligation of an external carotid artery. In the group were three serious and two minor postoperative infections. All healed without sinus formation and without extrusion or removal of a suture. One of these cases we are reporting in detail:

A Negro woman aged 50 entered Charity Hospital complaining of a large tumor on her head. Before surgical attack was made on the tumor it was decided to do a ligation of the left carotid. This was done, but considerable difficulty was experienced because of the large veins of the neck. A large lymph node was encountered and punctured with tissue forceps in its removal. The external carotid was ligated with no. 20 crochet cotton, all other vessels being ligated with transfixion ligatures of no. 50 plain cotton and the skin closed with cotton. On the fifth day the wound suppurated and by the eighth day the entire wound was open. Following irrigation with azochloramid, the granulations became clean and adhesive strapping was applied, the wound being closed entirely by the thirty-eighth postoperative day. No sutures were seen to come from or were removed from the wound. The temporal artery on that side remained occluded.

We recommend and have found satisfactory no. 60 plain cotton for the ligation of small vessels of the subcutaneous fat and other areas, no. 30 plain cotton or "heavy duty" mercerized cotton for approximation of the peritoneum and fascia. Where retention sutures are employed, no. 20 crochet cotton may be used. For through and through sutures of the abdominal wall no. 10 mercerized crochet cotton is best. Skin closure, when tension is not a factor, can be readily accomplished with no. 50 black mercerized thread. Black is used instead of white because the latter is somewhat difficult to find at times, owing to its becoming stained with blood. The cotton thread should be sterilized on a spool which does not expand in water as the cotton shrinks, causing the fibers to be broken. From a technical standpoint it is better to put all the sutures in one layer and then tie, as the tension is then transmitted to all the sutures, and besides time is saved. When there is an opportunity for serum to accumulate in the wound we have for some years used marine sponge compression bandages. We do not drain wounds unless there is gross contamination of abdominal wounds, in which a rubber tissue drain is placed down to the transversalis fascia and peritoneum. Because of its availability and the ease with which it can be sterilized, cotton thread would be a very satisfactory suture in field hospital in wartime.

S. Taylor, F. W.: *Surgical Knots and Sutures*, Surgery 5: 498 (April) 1939.

SUMMARY

1. Cotton thread has been found to be an extremely satisfactory suture, as it is easily sterilized and flexible and produces little tissue reaction and early fibroplasia.

2. Boiling for twenty minutes or autoclaving for fifteen minutes at 15 pounds pressure with the cotton wound on a rubber spool is recommended.

3. Of 196 operative procedures carried out, healing by primary intention occurred in 191.

4. There were three serious and two minor infections, all of which healed without sinus formation.

5. Halsted's rules concerning the use of silk were strictly adhered to in the use of cotton.

6. There is considerably less decrease in the tensile strength of cotton in tissue than that of catgut, silk or linen.

PLASMA PROTHROMBIN CONTENT OF BANK BLOOD

JERE W. LORD JR., M.D., AND JOHN B. PASTORE, M.D., NEW YORK

Recently Rhoads and Panzer¹ have stated that "bank blood" is an unsatisfactory source of plasma prothrombin for the treatment of patients with the hemorrhagic tendency associated with jaundice. Their results were based on the determination of the plasma prothrombin content of bank blood by the method of Quick.²

Quick's method for the determination of plasma prothrombin controls two of the four important factors which enter into the formation of a clot. An excess of calcium and thromboplastin are added to oxalated plasma in suitable amounts, and the time taken for a clot to form is considered the prothrombin time. In the Quick test no attempt is made to control the fibrinogen in the plasma. Linton³ and Moss⁴ have demonstrated that the fibrinogen in the plasma of man and dogs is normal in the hemorrhagic tendency associated with obstructive

Fig. 1.—Prothrombin content of forty-nine samples of bank blood.

jaundice. On the basis of their data, Quick⁵ considered it unimportant to control the factor of fibrinogen in the clotting process.

In 1935 Warner, Brinkhous and Smith⁶ described a method for the determination of plasma prothrombin which controlled

This study was carried out under a grant from the John and Mary R. Markle Foundation.

the factor of fibrinogen as well as the calcium and thromboplastin. Their test is a titration method involving several steps which are, briefly, as follows: Oxalated plasma is rendered fibrinogen free by the addition of freshly prepared thrombin. The prothrombin which is present in the fibrinogen-free plasma is then converted to thrombin by the addition of standard amounts of calcium and thromboplastin. To this thrombin is added standard solution of fibrinogen, and the time for a clot to form is determined. The fibrinogen-free plasma is diluted sufficiently to allow a clot to form in fifteen seconds after the addition of fibrinogen. The limits of error of the titration

Fig. 2.—Prothrombin content of a single sample of bank blood.

method of determining plasma prothrombin in the hands of Warner, Brinkhous and Smith and of ourselves is about 15 per cent.⁷ Either sodium citrate or sodium oxalate may be used as the anticoagulant.

The present study has been divided into two parts: first, the determination of the levels of plasma prothrombin in samples of bank blood after a suitable interval of storage employing the methods of Quick² and of Warner, Brinkhous and Smith,⁸ and second, observation of the influence on plasma prothrombin of exact refrigeration as employed in the blood bank and to be described by one of us (J. B. P.). The plasma prothrombin of blood from the blood bank is contrasted with the plasma prothrombin of blood stored in the usual laboratory refrigerator. Samples for prothrombin determination were taken directly from the blood as it was being administered to the patient. The blood in the blood bank was maintained at a temperature of 2 to 4 C. The data are shown in the table. As Rhoads and Panzer¹ observed, when the method of Quick is used the plasma prothrombin falls rapidly to less than 30 per cent of normal in less than one week. In contrast, the level of plasma

Plasma Prothrombin Content of Bank Blood*

Days	Blood Bank			Typical Ice Box		
	No. of Samples	Quick Test, %	W., B. & S. Test, %	No. of Samples	Quick Test, %	W., B. & S. Test, %
1-5	2	35	100	6	93	93
6-8	5	23	84	6	79	79
9-12	11	27	75	6	48	48
13-17	6	22	69
18-24	25	14	61

* The figures indicate percentages of normal content.

prothrombin of the same samples of bank blood when tested by the method of Warner, Brinkhous and Smith shows a gradual and gentle fall, remaining above 60 per cent of normal after three weeks of storage.

The explanation of the significant difference between the levels of plasma prothrombin of blood when determined by the method of Warner, Brinkhous and Smith on the one hand and by

the method of Quick on the other is not clear. The fibrinogen content of the samples of bank blood was determined by the method of Bancroft and his co-workers,⁸ and no significant change in the average level of fibrinogen occurred during the three weeks of storage. It is possible that after storage there are qualitative changes in the fibrinogen so that it does not react with thrombin as quickly or as completely as fresh blood.

In the table, plasma prothrombin of blood from the blood bank is contrasted with plasma prothrombin of blood stored in the typical laboratory electric ice box. There is only a slight difference, i. e. 5 per cent, in the level of plasma prothrombin stored by the two methods during the first week; but by the ninth to twelfth day there is a marked loss of plasma prothrombin in the inadequately refrigerated blood, the level falling to an average of less than 50 per cent in contrast to an average of 75 per cent for the properly stored bank blood.

Figure 1 is a spot graph of the plasma prothrombin levels, as determined by the method of Warner, Brinkhous and Smith, of the forty-nine samples of rigidly stored bank blood. During the first ten days no sample has fallen to as low a level as 60 per cent of normal, and not until the twentieth day does any sample show less than 50 per cent of normal. Figure 2 shows the plasma prothrombin levels of a typical specimen of bank blood followed over a period of twenty days.

SUMMARY

1. On the basis of the method of Warner, Brinkhous and Smith, bank blood is an adequate source of plasma prothrombin for about nine days. At longer intervals of storage the plasma prothrombin declines gradually, reaching the level of 61 per cent of normal by the end of the third week of storage.

2. Carefully controlled refrigeration of bank blood is an important factor in the preservation of plasma prothrombin.

THE QUANTITY OF BLOOD REQUIRED TO PRODUCE A TARRY STOOL

W. A. DANIEL JR., B.S., B.M., AND SHERMAN EGAN, B.S., B.M.
CHICAGO

This experiment was undertaken under the direction of Dr. A. C. Ivy to ascertain the quantity of blood which, when taken by mouth, will produce a tarry stool.

Ten healthy medical students were the subjects of the experiment. The procedure employed was essentially the drinking of venous blood drawn from the subject and subsequent gross examination for a tarry stool; that is, a stool which was black and glistening. No microscopic or chemical tests for blood were used, for the results of such an examination are not obtained in a patient's history. Progressively larger quantities of blood were taken by the subject until a tarry stool occurred. Sufficient time in each case was allowed for passage of the blood through the gastrointestinal tract before larger quantities were taken. Each subject was allowed to eat a general diet of his own choice; in addition, four of the students repeated the experiment while on a diet of milk and cream, which was used to obviate any possible blackening of the stool by a general diet.

Of the ten students who took the blood while on a general diet, one had a tarry stool after taking 50 cc., two with 60 cc., three with 70 cc. and four required 75 cc. of venous blood. A tarry stool was obtained with 55, 60, 70 and 80 cc. by the four students on the milk and cream diet. In two cases this amount of blood was the same as that required on a general diet; in the other two 5 and 10 cc. more of blood was required to produce a typical tarry stool on the general than on the milk and cream diet.

CONCLUSION

At least from 50 to 80 cc. of blood when taken by mouth is required for the production of a tarry stool.

12 West Walton Place.

7. The limits of error of the Warner, Brinkhous and Smith test of about 15 per cent refers to the test as run from day to day. When several samples are run at one time, the limits of error are less than 3 per cent.

THE NEW FEDERAL FOOD, DRUG AND COSMETIC ACT

A CONSIDERATION OF FEATURES THAT ARE OF
PARTICULAR INTEREST TO THE
MEDICAL PROFESSION

THEODORE G. KLUMPP, M.D.
WASHINGTON, D. C.

The Federal Food, Drug and Cosmetic Act was enacted into law on June 25, 1938. On that date the sections pertaining to new drugs, dangerous drugs and injurious cosmetics became effective. Other provisions became operative only to the extent that they may relate to the enforcement of the aforementioned sections. The act was to have become effective in its entirety on June 25, 1939, but meanwhile an amendment was enacted postponing the new labeling requirements until Jan. 1, 1940, or later under certain conditions.

The old Food and Drugs Act was passed in 1906 when social, economic and technologic conditions in this country were vastly different from those which obtain today. During the intervening thirty-two years repeated efforts to adapt food and drug legislation to changing conditions and the growing complexity of our national life were invariably successfully opposed until the act of 1938 was passed. It is generally conceded that this law, while inadequate and defective in certain respects, is a genuine improvement over the original act. From a long range point of view, the extent to which this improvement will be translated into actual accomplishment will depend largely on three factors: (1) the manner in which the provisions of the act are interpreted by the federal courts, (2) the extent to which Congress is willing to implement its enforcement through adequate appropriations and (3) the cooperation of scientific and professional groups and consumer groups.

Certain features of the new act should be of special interest to members of the medical profession. The Food, Drug and Cosmetic Act of 1938:

1. Brings under control drugs used in the diagnosis of disease and drugs intended to affect the structure or any function of the body [sec. 201 (g) (2), (3)]. (Under the old law, only substances intended to be used for the prevention, cure or mitigation of disease were classed as drugs.)

2. Brings therapeutic devices under control and subjects them to the same general requirements as are set up for drugs [sec. 201 (h), secs. 501, 502].

3. Brings all cosmetics except soap under control [sec. 201 (i)], outlaws cosmetics which may be injurious to users, except coal tar hair dyes, which must bear warning labels and carry adequate directions for preliminary testing of the skin [sec. 601 (a)] and prohibits false or misleading labeling on cosmetics [sec. 602 (a)].

4. Prohibits traffic in drugs and devices which are dangerous to health under the conditions of use prescribed in the labeling [sec. 502 (j)]. (The old act contained no prohibition against dangerous drugs or devices.)

5. Prohibits traffic in new drugs unless such drugs have been adequately tested to show that they are safe for use under the conditions of use prescribed in their labeling, and authorizes exemption from this

requirement of drugs intended solely for investigational use by qualified scientific experts [sec. 505].

6. Requires drugs intended for use by man to bear labels warning against habit formation if they contain any of a list of narcotic or hypnotic habit-forming substances, or any derivative of any such substance which possesses the same properties [sec. 502 (d)].

7. Requires the labels of nonofficial drugs to list the names of the active ingredients and in addition to show the quantity or proportion of certain specified ingredients. Authorizes regulations prescribing exemptions from this requirement when compliance is impracticable [sec. 502 (e)].

8. Requires the labeling of drugs and devices to bear adequate directions for use but authorizes regulations exempting drugs and devices from this requirement when it is not necessary for the protection of the public health [sec. 502 (f)].

9. Exempts a drug dispensed on the written prescription of a licensed physician and the label of which contains the name and place of business of the dispenser, the serial number and date of such prescription and the name of such physician from the labeling requirements relating to:

(a) Name and address of manufacturer and statement of quantity of contents [sec. 502 (b)].

(b) Declaration of the name of the drug or the common names of the active ingredients when the drug is fabricated from two or more ingredients, and declaration of the quantity of certain specified ingredients [sec. 502 (e)].

(c) Declaration of "Warning—may be habit forming," when the drug contains the substances mentioned in section 502 (d) or their derivatives but only in those cases in which the prescription is marked as not refillable or its refilling is prohibited by other laws [sec. 502 (d)].

10. Requires the labeling of drugs and devices to bear warnings against use in those pathologic conditions or by children when its use may be dangerous to health, or against unsafe dosage or methods or duration of administration or application, in such manner and form as are necessary for the protection of users [sec. 502 (f)].

11. Requires special precautionary packaging and labeling as the Secretary of Agriculture may determine to be necessary for drugs that are liable to deterioration [sec. 502 (h)].

12. Requires labels of official drugs—i. e. drugs recognized in the United States Pharmacopeia, National Formulary or Homeopathic Pharmacopeia of the United States—to reveal any differences of strength, quality or purity from the official standards [sec. 501 (b)]. (The old law requires merely that the label bear a true statement of the strength, quality and purity of the drug without showing the difference from the official standard.)

13. Makes the Homeopathic Pharmacopeia of the United States the legal standard for homeopathic drugs [sec. 201 (j), sec. 501 (b)].

14. Requires official drugs to be packaged and labeled as prescribed by the pharmacopeias and National Formulary [sec. 502 (g)].

15. Declares nonofficial drugs illegal if the standard of strength thereof differs from, or the purity or quality falls below, the standard claimed [sec. 501 (c)]. (The old law prohibits only those which fall below the strength claimed.)

16. Requires that antiseptics possess germicidal power [sec. 201 (o)].

17. Does not contain the fraud joker in the old law under which the government must prove that false claims of curative effect on the labels of "patent medicines" were made with wilful intent to deceive.

18. Proscribes the use of containers for food, drugs and cosmetics which may render the contents injurious to health [sec. 402 (a) (6), sec. 501 (a) (3), sec. 601 (d)].

19. Prohibits traffic in food, drugs and cosmetics which have been prepared or handled under insanitary conditions that may contaminate them with filth or cause them to contain any putrid or decomposed substance or that may render them injurious to health [sec. 402 (a) (4), sec. 501 (a) (2), sec. 601 (c)].

20. Forbids the use of uncertified coal tar colors in foods; also in drugs when used for coloring purposes only, and in cosmetics other than hair dyes [sec. 402 (c), sec. 501 (a) (4), sec. 601 (e)].

21. Proscribes slack filling of containers for food, drugs and cosmetics and prohibits the use of deceptive containers [sec. 403 (d), sec. 502 (i) (1), sec. 602 (d)].

22. Prohibits traffic in food which may be injurious to health [sec. 402 (a) (1)]. (The old law prohibited injurious food only when the poisonous substance was added.)

23. Prohibits the addition of poison to food except when such addition is required in the production thereof or cannot be avoided by good manufacturing practice; when added poisons are so required or cannot be avoided, tolerances are authorized, the amount being limited to a point insuring protection of public health [sec. 402 (a) (2), sec. 406 (a)].

24. Authorizes emergency permit control of food that may be injurious because of contamination with micro-organisms if public health cannot otherwise be protected [sec. 404]. Through the operation of this provision the continued distribution of such food, or food suspected of contamination, can be stopped until the situation is fully corrected.

25. Forbids traffic in confectionery containing metallic trinkets or which bears or contains any alcohol or nonnutritive article or substance except harmless coloring, harmless flavoring, harmless resinous glaze not in excess of 0.4 per cent, natural gum, and pectin [sec. 402 (d)].

26. Specifically requires label declaration of artificial coloring, artificial flavoring and chemical preservatives in food but exempts butter, cheese and ice cream from this requirement as far as artificial coloring is concerned [sec. 403 (k)].

27. Requires labeling of special dietary food to inform purchasers fully of its vitamin, mineral and other dietary properties [sec. 403 (j)].

28. Provides for the promulgation of a definition and standard of identity and a reasonable standard of quality and fill of container for each food but exempts from this provision fresh and dried fruits and vegetables, except avocados, cantaloupes, citrus fruits and melons [sec. 401, sec. 403 (g), (h)]. Butter is also exempt from this provision, but the act preserves the statutory definition and standard of identity for butter which became law in 1923 [sec. 902 (a)]. (The old law contains no authority for the establishment of definitions and standards of identity, and the authority to establish standards of quality and fill of container is limited to canned foods.)

29. Requires the labeling of food for which no definition and standard of identity has been fixed to disclose the ingredients by name, except spices, colorings and

flavorings, which may be declared simply as spices, colorings and flavorings. Authorizes regulations prescribing exemptions from this requirement when compliance is impracticable or results in deception or unfair competition [sec. 403 (i)].

30. Does not contain the "distinctive name" joker of the old law under which any mixture or compound of food not injurious to health could escape control.

31. Provides increased criminal penalties for violations [sec. 303].

32. Authorizes the federal courts to restrain violations by injunction [sec. 302].

EFFECT ON PRACTICE OF MEDICINE

How the new act will affect the practice of medicine is a question that has been asked by many physicians. While it is impossible to forecast to what extent the new act will ultimately aid the physician in his function of preventing and treating disease, one of the fundamental purposes of the law is to safeguard the public health. It may be pertinent to mention a few of the ways in which the act is directed toward this end:

The sections proscribing dangerous drugs and devices and injurious cosmetics and effecting more stringent control over deleterious ingredients in foods should bring about a lower general incidence of poisoning from these sources. It may be anticipated that the provisions which require disclosure of the active ingredients of drugs, adequate directions for use and warnings will aid the public in making more intelligent purchase and use of drugs. Similarly, the physician will be in a position to know the nature of the medication taken by his patients. Of particular importance is the protection provided by the act against the marketing of new drugs which have not been adequately tested for safety. The enhanced safeguards against variations in the strength, quality and purity of drugs should be of particular interest to those who administer them. Likewise, the requirement that the labels of foods offered for special dietary use bear adequate information to inform the purchaser fully as to its value, for such use will enable physicians more accurately to evaluate and advise their patients concerning such foods.

Enforcement of the Food, Drug and Cosmetic Act was entrusted to the Food and Drug Administration of the Department of Agriculture. It is to be particularly noted that this act does not include within its scope jurisdiction over advertising. In a separate bill, the so-called Wheeler-Lea Act, passed March 21, 1938, Congress specifically delegated the regulation of advertising of foods, drugs, devices and cosmetics to the Federal Trade Commission. Meats and meat food products are exempt from the provisions of the Food, Drug and Cosmetic Act to the extent that the Federal Meat Inspection Act is applicable to these products. Likewise the application of the Virus, Serum and Toxin Act of 1902 is not affected, modified or superseded by the act under discussion.

OTHER RESULTS

With the enactment of more effective regulation of foods, drugs, devices and cosmetics, the question of how this legislation will affect the work of the Council on Pharmacy and Chemistry, the Council on Foods, the Advisory Committee on Advertising of Cosmetics and Soaps of the American Medical Association and other similar groups has been raised. It has, in fact, been thoughtlessly intimated that the work of these councils would be in the main unnecessary. In a recent address, the Secretary of the Council on Pharmacy and Chem-

istry¹ pointed out the fallacies of such a concept. In his informal discussion of the topic he pointed out the respects in which the new Food, Drug and Cosmetic Act and the rules of the Council are similar in purpose, as well as the respects in which they differ in function. The protection of the public from adulterated, misbranded and dangerous drugs, devices, cosmetics and foods is a large and never ending task. It is fitting that groups such as the American Medical Association and the American Dental Association, which have an interest in public health and welfare, should participate in this work. In this as in other functions of a democratic form of government, public welfare is served best when there is a vigorous public interest and participation in the activities of government.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

SOBISMINOL MASS AND SOBISMINOL SOLUTION

During 1933, Hanzlik undertook to develop a soluble bismuth preparation intended for oral as well as intramuscular administration in the treatment of syphilis. A patent^{1a} was applied for by Hanzlik in 1936, and later the three manufacturers noted herewith were licensed by the Board of Trustees of Stanford University of California, assignee of the patent. The product originally called "Sodium Bismuthate Soluble"² was submitted to the Council on Pharmacy and Chemistry in 1936 for consideration under the names "Sodobismol" (E. R. Squibb & Sons), "Sodium Bismuthate Soluble-Cutter" (Cutter Laboratories) and "Sodium Bismuthate Soluble" (Eli Lilly & Co.). Subsequently the term "Sobisminol" was decided on as a suitable nonproprietary designation by Hanzlik, the respective manufacturers and the Council.

After preliminary consideration, Hanzlik and the respective manufacturers were informed that there was insufficient confirmatory evidence to warrant action by the Council at that time.

Shortly thereafter, Hanzlik reported to the Council on a small series of patients: Twenty-five had received oral treatment and fifty had been treated by injection. He indicated that data had been obtained on the absorption and excretion of bismuth after oral administration of sobisminol mass to several patients and that estimation of bismuth had been made on several hundred weekly specimens of urine. Subsequent material which formed the basis of later publications by Hanzlik, Lehman and Richardson² and by Sollmann, Cole and Henderson³ was also called to the attention of the Council. More recently, a number of articles have appeared in the literature furnishing evidence in confirmation and extension of the earlier work. The nature of this pharmacologic and clinical evidence is reviewed herewith.

CHEMICAL AND PHYSICAL PROPERTIES

It has been noted by both the A. M. A. Chemical Laboratory and by Hanzlik and his co-workers⁴ that sobisminol contains no free sodium

bismuthate⁵ but rather some unidentified bismuth complex. It has been stated that the bismuth of sobisminol remains in stable, anionic (electronegative) form in solution.² Hanzlik, Lehman and Richardson² discuss the preparation of two forms: a semisolid for oral administration and a solution to be used for injection and oral administration. The composition of the products to be marketed is described later.

The semisolid to be used for oral administration, termed "sobisminol mass," is a complex organic bismuth product the chemical nature of which has not been fully established. It is obtained by the interaction of 2 Gm. of sodium bismuthate, 4 Gm. of triisopropanolamine and 1 cc. of propylene glycol or similar ratio in larger amounts. Appropriate quantities of sodium bismuthate, triisopropanolamine and propylene glycol are thoroughly mixed and gradually heated to about 80 C., at which temperature an exothermic reaction occurs. When cool, the resultant mass is thoroughly mixed, tested, assayed and, if satisfactory, filled into capsules. The bismuth content of the finished product approximates 19.7 per cent. According to tests in the A. M. A. Chemical Laboratory, Sobisminol mass occurs as a red-brown to solid. The mass possesses an odor resembling and a bitter taste, with a sweetish, metallic in water and in alcohol, yielding a clear solution in either solvent. It is partially soluble in acetone, chloroform and ether. The pH of a solution of sobisminol mass, made by dissolving 1 Gm. in water sufficient to make a final volume of 10 cc., should not be above 11.9, as determined with a glass electrode.

The solution to be used for injection and oral administration termed "sobisminol solution" contains a complex organic bismuth product, the chemical nature of which has not been fully established. It is obtained by dissolving the products of the interaction of sodium bismuthate, triisopropanolamine and propylene glycol in a mixture of propylene glycol and water. Each cubic centimeter of sobisminol solution contains 0.5 cc. of propylene glycol, a part of which enters into a reaction with 0.03 Gm. of sodium bismuthate and 0.08 Gm. of triisopropanolamine, the remainder being water. Requisite quantities of sodium bismuthate, triisopropanolamine and a portion of the necessary propylene glycol are thoroughly mixed and allowed to react as in the preparation of sobisminol mass. The remainder of the propylene glycol and water sufficient to make the final volume are added when the reaction is complete. After mixing, the resultant solution is tested, assayed and filled into ampules containing 1 cc. and 2 cc., respectively, or bottles containing 50 cc. Each cubic centimeter of the final solution contains the equivalent of approximately 20 mg. of bismuth. Sobisminol solution occurs as a clear, dark brown-red mobile liquid. It possesses an odor resembling that of triisopropanolamine and a sweet, mildly metallic, taste. It is miscible with an equal volume of water or alcohol, yielding a clear solution. The specific gravity of sobisminol solution closely approximates 1.065 and the pH of the solution should not be below 11.1 or above 11.5, as determined with a glass electrode.

Sobisminol mass may be stored in a refrigerator; it remains stable at 38 C. Aqueous solutions of the drug do not precipitate serum proteins and may be boiled alone or with equal parts of serum without precipitation. Neither sobisminol mass in 10 per cent aqueous solution nor sobisminol solution is precipitated on the addition of equal volumes of solutions of 0.1 per cent hydrochloric acid or 0.5 per cent sodium bicarbonate, but both are precipitated by strong acids or alkali.²

PHARMACOLOGY

The pharmacologic effects of sobisminol mass and solution have been studied by Hanzlik and his co-workers.

ABSORPTION OF BISMUTH

Systemic absorption of sobisminol (mass or solution) in animals was demonstrated by determining toxic effects and fatalities with large doses,⁶ by the rate of disappearance of bismuth compounds from sites of injections⁷ and by their appearance in the urine after administration by all routes—intramuscular, gastric or oral.

The dissection of muscles of rats and guinea pigs receiving single and repeated therapeutic and fatal doses of sobisminol solution intramuscularly failed to reveal precipitates or depots of bismuth or its compounds in injected regions.⁸ Chemical analyses of these muscles by a method recently described (sensitive to about 0.04 mg. of bismuth per hundred cubic centimeters⁹) indicated practically complete absorption at the end of one hour. Hanzlik and his associates¹⁰ made quantitative studies of absorption of bismuth from the ligated stomachs and ligated loops of intestine of rabbits and white rats after injection of sobisminol solution. Although the number of results was not large enough to permit generalizations, approximately 50 per cent of the sobisminol solution placed into empty ligated intestine or stomach was found to be absorbed in from one to eight hours. A limit of bismuth absorption was reached at the end of from twenty to twenty-four hours, and in searching for the cause of the limit they found that there were relatively large quantities of bismuth in the intestinal or stomach wall.¹¹

Absorption of sobisminol (mass or solution) in man, as evidenced in clinical studies, appears to be rapid and sufficient to maintain antisyphilitic levels of bismuth concentration in the body.¹² Moreover, x-ray examination of gluteal regions in patients each receiving adequate antisyphilitic therapy in the form of injections of sobisminol solution failed to reveal shadows.²

DISTRIBUTION OF BISMUTH

Studies of bismuth distribution¹³ in the tissues have supplied further evidence of systemic absorption of sobisminol. Analysis of the kidneys,

5. Sodium bismuthate is such a "strong" oxidizing agent that it could not have existed in such a mixture as proposed without rapidly oxidizing the other substances present.

blood, liver and brain¹⁴ of experimental animals receiving sobisminol solution by injection into ligated viscera and by gastric administration indicated the presence of bismuth compounds. However, only from 30 to 40 per cent of the animals showed it in the blood and muscles, and only about 15 per cent in the brain.⁸ Naturally, the greatest quantities of bismuth were present in the kidneys, since bismuth is excreted through those organs.

Sustained intramuscular medication in animals resulted in consistently higher quantities of bismuth in all tissues; however, different tissues varied greatly from animal to animal on the same therapeutic regimen. The tissues analyzed may be arranged in descending order of bismuth content as follows: kidney, liver, muscle, blood and brain.⁸ Following intensive therapeutic regimens, the bismuth content of the blood was generally of the order of 0.02 to 0.03 mg. per hundred cubic centimeters, and of the brain from a trace up to 0.05 mg. per hundred grams. The bismuth content of the liver was of the general order of about 0.03 to 0.06 mg. per hundred grams. Single doses yielded much smaller and inconstant concentrations, which were not discussed. Failure to find bismuth in the blood consistently was attributed to the time interval between injection of sobisminol solution and removal of tissues for analysis.

The ingestion of aqueous 0.1 to 0.3 per cent solutions of sobisminol mass by rabbits for periods of two to three months resulted in the appearance of bismuth always in the kidneys, livers and muscles and, in about one half of the animals, in the brains. Such oral administration of sobisminol solution was shown to produce a blood concentration of bismuth comparable to that after intramuscular injection.

The distribution of bismuth in man after treatment with sobisminol (mass or solution) is attested by antisyphilitic concentrations of bismuth in the blood¹⁴ and urine¹⁵ and by the finding of bismuth in cerebrospinal fluid.¹⁶

EXCRETION OF BISMUTH

Gastric administration of sobisminol solution to nine rabbits receiving doses equivalent to single and multiple (three to twelve) therapeutic doses resulted in prompt, definite and sustained urinary excretion of bismuth,² beginning the day following administration and reaching a peak on about the fourth day after single doses and on the tenth and twenty-eighth days after from three to twelve doses, respectively. Quantities of about 0.3 mg. of bismuth excreted daily were common. The total amounts of bismuth excreted were about as follows: 0.075 per cent of a total of 48 mg. of bismuth per kilogram, administered as a single dose; 2 per cent of a total of 64 mg. per kilogram, in three doses in one week; 0.3 per cent of a total of 576 mg. per kilogram in one month.

Hanzlik, Lehman, Richardson and Van Winkle¹¹ found that a considerable portion of the bismuth of sobisminol (mass or solution) administered orally escapes with the feces. Considerable amounts of bismuth were unaccounted for and presumably retained in the body (partly in the intestinal wall), supposedly to be excreted gradually over long periods in small quantities which could not be estimated. Fecal elimination of bismuth appeared to decrease as the urinary excretion of bismuth increased, and vice versa.

Comparable results on urinary and fecal excretion of bismuth have been reported by Stratton,¹⁷ who found, however, that fourteen daily gastric doses of sobisminol solution, each equivalent to 20 mg. of bismuth per kilogram of body weight, raised the total urinary excretion of bismuth to only about five times the amount excreted after a single dose, further demonstrating the limit of excretion.

Intramuscular injections of sobisminol solution resulted in greater urinary excretion of bismuth in both animals and human subjects than was obtained by oral administration.² In rabbits receiving single doses of 0.4 mg. of bismuth per kilogram, excretion of bismuth began promptly the next day, the peak being reached on the third day, the maximum daily excretion being about 0.15 mg. and the duration thirty-five days. The total excretion was 37 per cent of the total bismuth injected. After three such doses injected in one week, the peak occurred on the fifth day, the maximum daily amount of bismuth excreted being 0.5 mg., the duration being about twenty days and the total excretion 30 per cent of the total administered. After twelve such doses in one month, the peak was reached on the sixteenth day, the maximum daily amount being 0.6 mg., the duration fifty days and the total excretion 42 per cent of the total administered.

The excretion of bismuth after oral and intramuscular administration of sobisminol to man has been studied by several groups of investigators. Hanzlik and his co-workers¹⁸ and, more recently, Sollmann, Cole and Henderson³ have studied bismuth excretion after oral administration, while Hanzlik and his co-workers¹⁹ have studied excretion after intramuscular injection of sobisminol.

Twelve complete observations on seven different persons lead Hanzlik, Lehman, Richardson and Van Winkle⁴ to conclude that the oral administration of sobisminol mass and solution to man resulted in prompt and definite excretion of bismuth in the urine, although most of the bismuth was expelled in the feces. The daily excretion of bismuth in the urine, after oral administration of 1.2 or 1.8 Gm. of sobisminol mass, is comparable to that observed after intramuscular injection of soluble bismuth compounds and above that occurring after administration of the insoluble compounds. It was observed that the urinary excretion of bismuth was demonstrable one-half hour after oral administration. Such excretion was found to vary directly with the dose, to manifest a cumulative tendency and to outlast the period of administration. However, the total urinary bismuth was but a small portion of the total amount of sobisminol administered—about 0.3 per cent for doses of 1.2 or 1.8 Gm. Urinary excretion was usually retarded or reduced by the presence of food and varied considerably with the individual. The median daily contents of bismuth of 660 weekly specimens of urine of patients receiving sobisminol mass were found to be, roughly, a thousandth of the amount of bismuth administered daily.

Sollmann, Cole and Henderson,³ in a study of urinary excretion of bismuth during clinical oral administration of sobisminol mass to patients, found that doses of three capsules and of nine capsules daily for three weeks gave curves for urinary excretion resembling closely in course and degree those given by intramuscular injection of the water soluble and oil soluble compounds. The rise of excretion at the beginning of treatment and the decline after its discontinuance were as prompt as with preparations for intramuscular use. The level of excretion for the lower dose ranked just below that for other preparations; that for the higher dose ranked just above them, its median total excretion being about twice the median excretion obtained by other methods. The dose, however, had to be considerably higher with oral than with intramuscular administration. The total urinary bismuth excreted amounts to about 0.5 per cent of the quantity administered.

Bismuth excretion, after clinical intramuscular injection of sobisminol solution, indicates a sustained circulation of bismuth compounds through the body.²⁰ Daily urinary excretion of bismuth compounds fluctuates considerably but excretion continues for long periods, e. g. twenty days after one dose, thirty-four days after three doses and about sixty-four days after twelve doses. Total excretion of bismuth was about 35 per cent of the dosage administered. Fecal excretion of bismuth varied daily but amounted to about one ninth of that in urine. From 60 to 70 per cent of the bismuth injected as sobisminol solution remained unaccounted for, as in the case of rabbits.²¹

TOXICITY

The toxicity of sobisminol administered orally as sobisminol mass and intravenously or intramuscularly as sobisminol solution has been determined.⁹ It has been stated that, on the whole, the toxicity of sobisminol, intravenously and intramuscularly, compares favorably with that of other water soluble bismuth compounds used in the treatment of syphilis.⁹ Fatal intramuscular doses of sobisminol solution in milligrams of bismuth per kilogram of animal were 175 in white rats and 77 in rabbits. The 50 per cent mortality dose was 105 mg. of bismuth per kilogram for white rats.

Intravenous fatal doses of sobisminol solution in milligrams of bismuth per kilogram were found to be 17.5 in rats and 8.4 in rabbits.² The 50 per cent mortality dose was 14 in rats. Later it was concluded that the majority of white rats would die from intravenous injections of sobisminol solution equivalent to 8 mg. of bismuth per kilogram, and rabbits from doses equivalent to 4.2 mg. of bismuth per kilogram.²¹

Sobisminol solution was administered gastrically to 113 white rats, twenty-one rabbits, ten cats and ten dogs.⁹ The fatal gastric dose in white rats was 24 cc. of sobisminol solution, or 504 mg. of bismuth per kilogram; in rabbits 17 cc., or 357 mg. of bismuth per kilogram; in cats and dogs about 140 mg. of bismuth per kilogram. The 50 per cent mortality doses in rats and rabbits were quite similar; i. e. from 14 to 14.8 cc. of sobisminol solution, or from 294 to 310.0 mg. of bismuth per kilogram. It was stated that the number of cats and dogs used was too small and the contributory effects of central nervous depressants too uncertain for accurate determination of the fatal doses.

Hanzlik and his co-workers²² and Lehman and Dock²³ have investigated the effects of continued oral medication with sobisminol mass in animals. Dilutions of sobisminol mass corresponding to 0.2, 0.3 and 0.5 per cent and from 0.1 to 0.6 per cent were ingested by rats and rabbits, respectively. Aqueous 1 per cent solution of sobisminol mass was not taken voluntarily by rabbits.² With increase in concentration and total dosage of sobisminol mass, increased losses of body weight and reduction in food intake of rabbits was noted. These tendencies, however, were present to about the same degree in rabbits on a bismuth free mixture²⁴ of the other ingredients of sobisminol. Pathologic changes in the heart, liver and kidneys of some animals on both doses of sobisminol and bismuth free mixture were found to be negative or negligible.⁷ Hyperemia and congestion of the alimentary tract were observed in animals receiving doses of sobisminol solutions or bismuth free mixture in doses of toxic strength.² Renal changes resembling those due to mercury in fatal doses resulted from like doses of sobisminol solutions; but only transient renal changes, unaccompanied by progressive alteration, were observed after smaller doses.

A study of the toxicity of the ingredients of sobisminol, other than the bismuth compound, indicated that any contribution of these ingredients alone to the toxicity of intravenous and intramuscular injections of sobisminol in animals must be practically negligible.²⁴ It should be noted, however, that considerations of the contribution of possible oxidation products produced in the preparation of sobisminol mass and sobisminol solution to the toxicity of the drug have not been published.

The nonbismuth constituents of sobisminol, dissolved in water and water alone, formed a blank test control on the results with sobisminol in animals living under otherwise similar conditions. Solutions containing 0.8 per cent triisopropanolamine and 5 per cent propylene glycol had practically no demonstrable effects on growth, body weight and daily food consumption in rats, and the daily volume drunk approximated that of water in the controls.

It has been shown that continued voluntary drinking of 0.3 per cent sobisminol solution by growing rats does not lead to the alteration of bone growth.²⁵ Two pregnant rats, and later their offspring, were allowed to drink aqueous 0.3 per cent sobisminol intermittently. On examination, the gross and microscopic structure of the bones showed no differences from controls. Bismuth compounds were found in the bones, soft tissues and pooled urines of these animals. Such results with effective doses of sobisminol prompted the discontinuance of further experimentation in this direction.²⁶

SIDE EFFECTS

Occasional incidence of slight and local edema and hyperemia were noted by Hanzlik, Lehman and Richardson²⁷ after the injection of large or toxic doses of sobisminol solution in animals but not, however, after doses of therapeutic order. Pain was not apparent.

Evidence of local irritation, indicated by vomiting, was present in cats and dogs given large doses of sobisminol solution gastrically. Tolerance was stated to be good when antiemetic drugs were used to avoid expulsion. Rodents tolerated the solution without emesis and stools showed no evidences of intestinal irritation, i. e. no diarrhea or bloody

Hanzlik, Lehman and Richardson²⁷ initially reported that, of a group of ninety-seven male and female patients receiving doses of 1 cc. of sobisminol solution intramuscularly, 61 per cent complained of transient stinging and burning for about ten minutes or less, 13 per cent of pain or soreness for one hour, and 26 per cent for from one to three days. The injection of similar doses of an aqueous solution containing about 50 per cent of propylene glycol and 8 per cent of triisopropanolamine gave rise to a similar distribution of complaints, although less acting was apparent. A decrease in the number of such complaints in a group of 260 patients was noted after reduction of the triisopropanolamine content of sobisminol to 5 per cent. Persistent soreness, swelling, abscesses, induration and similar evidences of irritation were not apparent, although some latent soreness was manifested occasionally.

With sobisminol mass, Meininger and Barnett²⁵ observed that 37 per cent of 192 patients showed some form of reaction, 65 per cent having mild gastric reactions. Patients taking the preparation during the first week noted symptoms of fullness, nausea and occasional vomiting. There were four cases of acute stomatitis, but these patients later were able to take the remedy. Occasionally patients would complain of severe burning sensations in the esophagus, particularly if they did not take liberal amounts of water with the preparation. No kidney damage was noted. Five patients were forced to stop the preparation because of severe gastrointestinal upsets and five were changed to other drugs because the preparations were not being taken.

Scholtz, McEachern and Wood²⁸ encountered difficulty from gastrointestinal intolerance in the oral treatment of ninety patients with three and later two capsules of sobisminol mass three times a day. Thirty patients experienced nausea and vomiting. There was bismuth "grip" in ten, anorexia in eleven and diarrhea in six. There were ten cases of stomatitis, which usually did not interfere, but three of these cases were so severe that it was necessary to stop the sobisminol capsules. Seven patients had a bismuth line. In this study also there was no evidence of prolonged therapy, thirty-eight received the drug for two months or more without interruption. Nine were unable to take more than four capsules a day. Five took the drug daily for more than a year without consequent symptoms. There seemed to be no tendency to cumulative toxic effects.

ANTISYPHILITIC EFFECTS

Hanzlik²⁷ found that the curative effects of injections of sobisminol solution in experimental syphilis were apparently equal to those obtained by the use of other bismuth preparations. Clearing of organisms from lesions after single doses of 10, 20 and 30 mg. per kilogram occurred in sixteen, seven and five days, respectively, and healing in thirty-five, sixteen and eleven days, respectively.

Clinical evidence of the antisiphilitic action of sobisminol mass and sobisminol solution has been reported by Hanzlik, Lehman and Richardson²⁷, Sollmann, Cole, Henderson and others,²⁸ Meininger and Barnett,²⁵ Scholtz, McEachern and Wood,²⁸ and Kay and Fricke.²⁹ The effects of sobisminol solution alone or in combination courses with arsenicals, administered by the intramuscular route, appeared to be equivalent to the effects with other bismuth products alone or with arsenicals. Oral administration of sobisminol mass resulted in the rapid clearing of lesions in secondary and tertiary syphilis. It should be noted, however, that these authors concluded that none of the patients had been followed long enough clinically for an adequate evaluation of the drug.

Sollmann, Cole and Henderson²⁸ have suggested combination courses of sobisminol solution and bismuth subsalicylate in oil as a means of obtaining an initial high concentration of bismuth in the treatment of patients with acute syphilis who are sensitive to arsenicals. Two series of three patients each, one iodobismutol with saligenin and sobisminol, respectively, were given three injections of the preparations the first week, two injections the second week, and one injection the third week. The median urinary excretion curve of the series on sobisminol was shown to have a higher urinary bismuth excretion than the series on iodobismutol with saligenin and also a more prolonged excretion after the injections had ceased. Moreover, when the two preparations were used in conjunction with intramuscular injections of bismuth subsalicylate in oil it was found that the median urinary bismuth excretion of a series of patients on sobisminol and bismuth subsalicylate in oil showed a higher and more prolonged excretion than a like series of patients on iodobismutol with saligenin and bismuth subsalicylate in oil.

Sollmann, Cole and Henderson²⁸ also administered three capsules equivalent to 420 mg. of bismuth, three times a day to three patients with primary and two with secondary syphilis. Spirochetes disappeared from lesions in a median of seven days. Moreover, excretion of bismuth after oral administration of sobisminol capsules was found to be higher than after administration of most bismuth preparations by any route.

Scholtz, McEachern and Wood²⁸ at first administered three capsules of sobisminol three times a day, later reducing the dose to two capsules three times a day, in a series of eighty cases of various types of syphilis. In cases of early syphilis, sobisminol mass was never used for more than two weeks without use of arsenicals. In five cases of seropositive primary

syphilis, dark fields were negative in a median of five days, with extremes of two and eight days. Lesions became involuted in a median of fourteen days, with extremes of ten and twenty. In twenty-seven cases of secondary syphilis the lesions of twenty-two were completely involuted in an average of twelve days, the lesions of ten patients taking two capsules three times a day were completely involuted in about thirteen days, and of twelve patients taking three capsules three times a day, in about twelve days. The small advantage of the larger dose was, however, counterbalanced by the lack of gastrointestinal symptoms when the smaller dose was used. The tertiary lesions of six patients involuted in thirty-one days, and squamous palmar lesions in thirty-three days. A large gumma of the soft palate disappeared in twenty days. These authors also believed that sobisminol would eventually prove to be of value in syphilis of the soft tissue system. One important point that is brought out is the evidence of sustained therapeutic effects from the drug when it is administered orally. If, however, treatment with sobisminol mass by mouth is stopped, the antisiphilitic effect appears to stop. In two cases of secondary syphilis, complete involution occurred in about two weeks. Because of nonattendance, the patients were not placed on arsenical treatment and it was noted that reactivation and relapse of the processes occurred within a period of two or three weeks.

Meininger and Barnett²⁵ noted that the disappearance of spirochetes in twenty-nine cases of primary syphilis usually occurred in about four days when three capsules of sobisminol mass three times a day were being taken. In four other cases they were still present at the end of fourteen days, at which time arsenical therapy was instituted. Primary syphilitic lesions involuted in an average of about ten days. Secondary lesions involuted in about the same length of time in twenty-six cases, while eleven additional cases of secondary syphilis were not entirely free at the end of fourteen days when nearsphenamine was started. The late lesions of syphilis required about 4.5 weeks of treatment with sobisminol capsules before involution occurred. Treatment with sobisminol capsules alone was continued for an average of about five months with seventy-three patients having late syphilis, more than six months with twenty-three patients, and more than twelve months with seven patients. Serologic reversal was noted in three cases: one reversed at four months, one at seven months and one was 2 plus when treatment was stopped at the end of ten months, becoming negative three months later.

Nineteen-three of their patients were treated with sobisminol mass in a form of combination course with nearsphenamine similar to that described by Beckh and Barnett³¹ for iodobismutol with saligenin. A comparison of the results obtained by this method in thirty-six patients in the primary stage of syphilis, with fifty-eight patients on nearsphenamine and iodobismutol with saligenin, indicated that sobisminol was superior in the production of serologic reversal and in the prevention of nerve involvement. Relapse was noted, however, in 12 per cent of the sobisminol-nearsphenamine group and in 11 per cent of the iodobismutol with saligenin group. Relapses were clinical in type in eight of the first group and four of the second group, serologic only in one of the first group and five of the second group. The average time of the occurrence of relapse in the first group was fourteen months and in the second group eighteen months. The authors stated that the patients in the sobisminol group were still in the potential relapse period and more were to be expected. Only seventeen of the sobisminol group had been followed longer than that if the period of observation for the sobisminol group had been longer it would compare less favorably with iodobismutol with saligenin in the prevention of relapse. They express the opinion that the occurrence of relapse in the two groups may be related to the treatment patterns that were used.

Kay and Fricke²⁹ have reported the use of sobisminol mass in five cases of late syphilis, in four of which they used a dosage of one capsule three times a day until from 300 to 1,200 capsules (from 70 to 166 Gm. of bismuth) were employed. Symptomatic and serologic improvement appeared in all four patients. Tolerance was found to be good, and, in spite of the length of the period of treatment, serious reactions were rare.

COMMENT

In view of the evidence, it would appear that sobisminol solution administered by the intramuscular route (a) exerts a definite antisiphilitic effect in experimental syphilis in the rabbit in doses of about 5 mg. per kilogram of body weight; (b) exerts a definite curative effect in experimental syphilis in the rabbit in a minimum curative dose of about 7 mg. per kilogram of body weight; (c) causes the disappearance of Spirochaeta pallida from chancres and condylomas of human beings in a period of from four to seven days; (d) acts to clear primary syphiloderms in about ten days, secondary syphilitic lesions in an average of about fourteen days, and tertiary syphilitic lesions in about thirty days; (e) acts satisfactorily in causing the reversal of the positive serologic blood reaction; (f) is moderately well tolerated after local injection; (g) produces a urinary excretion of bismuth as high as or higher than any other bismuth compound now employed in the treatment of syphilis, and (h) is followed by no greater incidence of relapse than after administration of other bismuth compounds. From the foregoing it is apparent that sobisminol solution offers a means of obtaining, by injection treatment, the systemic effects of bismuth in the treatment of syphilis.

In evaluating a bismuth compound which is to be administered orally, there are certain disadvantages which must be considered. Thus, with sobisminol mass a large number of the patients have gastrointestinal upsets, occasionally severe enough

to cause discontinuance of the drug;³² bismuth stomatitis is seen occasionally;³² a bismuth line is not rare.³⁶ There appears to be a tendency for some individuals to neglect their treatment as soon as they begin to feel better. Some of the patients examined by Meininger and Barnett²⁵ were found to have no bismuth in the urine, but it is believed that they were patients who had neglected the treatment. When injections are being given at stated intervals, the patient arranges for this treatment, knows when he is due for it and usually appears. On the other hand, if he is simply given some capsules to take, he may forget to take them or he may leave them at home and in that way be negligent in their use. Moreover, because of gastrointestinal intolerance the patient may become discouraged in the early stages of his syphilis at a time when treatment is most necessary. These factors acquire greater significance when it is considered that no sustained bismuth effect is derived from the use of sobisminol capsules, judging by the rapid drop of urinary bismuth excretion as soon as the capsules are stopped.³⁰ It is not surprising, therefore, that Scholtz, McEachern and Wood²⁶ noted two cases of relapse in early syphilis within two weeks after sobisminol capsules were stopped. Meininger and Barnett²⁵ also speak of this danger.

The relapse tendency when oral bismuth as a medication is employed is unfortunate, because it is in the first stages of syphilis that the relapses are most frequently seen. If a bismuth preparation is employed which allows the antisiphilic effect to cease soon after its administration is stopped, with no bismuth depots in the body, there is more danger of relapse than when continuous bismuth injections are carried out.

Finally, there is danger of self medication from the use of sobisminol mass. In such case an individual, unaware of the true character of the syphilis, may use sobisminol mass for a time, perhaps not in the proper dose, until he feels better, and then stop further treatment. As a result, an early infectious relapse and the consequent spread of the disease to other persons might occur.

It must be noted that the administration of sobisminol mass in capsules by the oral route² (a) results in an effect comparable to sobisminol injection therapy in sterilizing syphilis in rabbits and in destroying organisms in local chancres; (b) produces rapidly, in a dose of three capsules three times a day, a high urinary bismuth excretion, comparable to that of any other bismuth compound studied thus far; (c) causes primary syphiloderms to clear in about ten days, secondary lesions in about fourteen days and tertiary lesions in about thirty days; (d) results in satisfactory action in reversing positive serologic tests, and (e) exerts a definite action in the treatment of syphilis, clearing chancres and condylomas.

There is a definite place for oral therapy with sobisminol mass in the treatment of syphilis, although probably not so much in the early stages as in the latent period or in the later stages of the disease. It should be useful in certain early cases of syphilis to provide continuity when conditions necessitate the patient's being absent from the physician for a matter of a week or more. It is suggested, however, that intramuscular therapy is preferable in all early syphilis, if it is possible, for the purpose of maintaining continuous therapy, if for no other reason. Attention is directed to the fact that no bismuth depot is established when the product is administered solely by the oral route. From the experimental and clinical evidence described, it must be noted that the last course of bismuth therapy should be given as a series of insoluble injections, in order to establish bismuth depots for continuation of sustained bismuth effects.

The product has been before the Council on Pharmacy and Chemistry for approximately three years, during which time there was much consideration given by all concerned. The Council appreciated the cooperation of Dr. Hanzlik and his group and their decision not to permit commercial promotion of the product unless it was accepted by the Council. Three firms have submitted the product and have agreed to market it in conformance to the rules of license laid down jointly by the board of trustees and the department of pharmacology of Stanford University and with the rules of the Council.

The Council voted to include Sobisminol Solution and Sobisminol Mass in New and Nonofficial Remedies with the understanding, in the case of the latter, that all precautions will be taken against its use for self medication,³³ and also voted to accept brands of the product.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

SOBISMINOL MASS.—A complex organic bismuth product the chemical nature of which has not been fully established. It is obtained by the interaction of sodium bismuthate, triisopropanolamine and propylene glycol. It contains between 19.25 and 20.25 per cent of bismuth.

Actions and Uses.—Sobisminol mass is proposed in the treatment of syphilis and is intended for use by the oral route. It is particularly indicated for those patients unable to undergo intramuscular bismuth therapy and to supplant therapy by that route for patients compelled for a time to be out of contact with their physician. Again it may be indicated in certain other types of syphilis, e. g., congenital and latent syphilis. It is to be emphasized that it is too dangerous a drug to be employed by the patient without the careful supervision and direction of his physician, and it is sold only on prescription. In the first few days of therapy the patient should be carefully supervised and later watched for evidence of gastrointestinal upsets and of bismuth intoxication.

Dosage.—Adult dosage, from two to three capsules three times a day, taken with plenty of water, at 10 a. m., 3 p. m. and 8 p. m. Each capsule represents 150 mg. of metallic bismuth. Unless contraindications arise, such therapy may be continued for from ten to twelve weeks and represents a course of bismuth therapy. For children the dosage may be cut down to one capsule three times a day, or a 75 mg. capsule three times a day for a young child.

Sobisminol mass occurs as a red-brown to chocolate-brown colored pasty mass, possessing an odor similar to triisopropanolamine and a bitter taste, with a sweetish, metallic after-taste. It is soluble in water and alcohol, partially soluble in ether and acetone. The pH of a solution made by dissolving 1 Gm. of sobisminol mass in sufficient distilled water to make a volume of 10 cc. should not be above 11.9 as determined with a glass electrode.

Dissolve 1 Gm. of sobisminol mass in 10 cc. of water and halve the solution; to one portion add 5 cc. of 0.5 per cent sodium bicarbonate solution; to the other portion add 5 cc. of 0.1 per cent hydrochloric acid; neither solution yields a precipitate within fifteen minutes.

Dissolve 2 Gm. of sobisminol mass in 100 cc. of water; boil a 5 cc. portion: the solution remains clear and unchanged. To a separate portion of 1 cc. add 10 cc. of water and 1 cc. of 5 per cent sodium iodide 1 cc. solution: the solution remains clear. To another 1 cc. portion add 1 cc. of diluted hydrochloric acid, 5 cc. of water and 5 cc. of hydrogen sulfide solution: a black precipitate forms; to another 1 cc. portion add 3 cc. solution of diluted sulfuric acid and 1 cc. of 5 per cent sodium iodide solution: a red precipitate forms. To a 20 cc. portion add 2 cc. of nitric acid, adding more nitric acid dropwise, if necessary, until the solution is clear; divide into two equal parts; retain one part as a control and add 2 cc. of silver nitrate solution to the other part: when compared with the control, not more than a trace of turbidity is apparent (chloride). To another 20 cc. portion add 2 cc. of hydrochloric acid, adding more hydrochloric acid dropwise, if necessary, until the solution is clear; divide into two equal parts, retain one part as a control and add 2 cc. of barium chloride solution to the other part: when compared with the control, not more than a trace of turbidity is apparent (sulfate).

Transfer about 5.0 Gm. of sobisminol mass, accurately weighed, to a 100 cc. volumetric flask, add water to the mark and shake the contents thoroughly. Determine the nitrogen content of an accurately measured 10 cc. portion according to the method described in Methods of Analysis of the Association of Official Agricultural Chemists, fourth edition, p. 24, articles 22 and 23. In the procedure add 0.1 Gm. of anhydrous copper sulfate and continue the digestion for a period of two and one-half hours after the solution becomes clear. The amount of nitrogen is not less than 3.60 per cent nor more than 4.40 per cent.

Dissolve about 0.6 Gm. of sobisminol mass, accurately weighed, in 100 cc. of water and rapidly add 8 cc. of concentrated nitric acid. Add

33. In this connection it may be pointed out that the licensees have made the following agreement with Stanford University:
"Neither Licensee nor his agents, in carrying out the sale and distribution of said products shall:

- Furnish to retailers or condone or encourage use by retailers of any counter advertising or counter displays of said products;
 - Advertise said products directly to the public by advertisements in magazines or newspapers of general circulation or by printed circulars distributed to the general public;
 - Condone or encourage in any way "over the counter" sales of said products to the public except through licensed pharmacists or prescriptions of licensed physicians.
- Licensees shall use its best efforts to maintain distribution of said products exclusively through licensed pharmacists on prescription of licensed physicians, and to prevent over the counter sales of said product to the public."

32. Meininger and Barnett.²⁵ Scholtz, McEachern and Wood.²⁶

two drops of methyl red solution and then add ammonia water until the solution just turns yellow; add 3 cc. of nitric acid, heat to boiling and slowly add, with cautious stirring, 50 cc. of 10 per cent diammonium phosphate solution; dilute to a volume of about 400 cc. with boiling water and allow the mixture to stand for one hour at 80 C. Collect the precipitate on a tared Gooch crucible by first filtering the supernatant liquid, then wash the precipitate through the crucible, and finally complete the transfer of the precipitate by means of cold water; dry the crucible and contents at 110 C. for one hour, suspend the crucible within another crucible and ignite gently for forty-five minutes, adjusting the flame so that the bottom of the lower crucible is heated to dull redness; cool the crucible and contents and weigh the ignited material as bismuth phosphate; use the factor 0.6875 for the conversion of bismuth phosphate to bismuth; the amount of bismuth found corresponds to not less than 19.25 per cent nor more than 20.25 per cent.

Propylene Glycol. The propylene glycol used in the preparation of sobisminol mass and sobisminol solution conforms to the New and Non-official Remedies standards for this substance, which see.

Sodium Bismuthate. The sodium bismuthate used in the preparation of sobisminol mass and sobisminol solution conforms to the following tests for identity and purity:

Sodium bismuthate occurs as a nearly odorless, yellow-brown powder containing not less than 80 per cent of NaBiO_3 .

Dissolve 1 Gm. of sodium bismuthate in a mixture of 5 cc. of hydrochloric acid and 15 cc. of water; a slightly turbid, yellow solution results. Agitate 2 Gm. of sodium bismuthate with 50 cc. of water frequently during one hour; the resultant suspension is alkaline to phenolphthalein; filter, rejecting the first few cubic centimeters; evaporate 25 cc. of the clear filtrate in a tared dish, dry the residue at 120 C. and weigh; the weight of the residue is not more than 0.003 Gm.

Boil 2.5 Gm. of sodium bismuthate and 40 cc. of water for ten minutes, cool, dilute to 50 cc. with water, mix well, filter and divide into 10 cc. portions; to one portion add 0.5 cc. of nitric acid and 1 cc. of silver nitrate solution; the turbidity should not be greater than that produced in a control containing 0.025 mg. of chloride ion (*chloride*); to another portion add 0.5 cc. of normal hydrochloric acid, filter, if necessary, and add to the clear filtrate 1 cc. of barium chloride solution; the turbidity should not be greater than that produced in a control containing 0.05 mg. of sulfate ion (*sulfate*).

Heat 0.5 Gm. of sodium bismuthate with 3 cc. of sulfuric acid until fumes of sulfur trioxide appear, then complete the test for arsenic according to the method described in the U. S. P. XI: The arsenic content should not exceed 2 parts per million.

Dissolve about 0.25 Gm. of sodium bismuthate, accurately weighed, in 8 cc. of nitric acid, dilute with 100 cc. of water and continue the assay for bismuth as directed under sobisminol mass; the amount of bismuth found corresponds to not less than 66.5 per cent nor more than 72.5 per cent.

Transfer about 0.7 Gm. of sodium bismuthate, accurately weighed, to a flask and add 25 cc. of acid ferrous sulfate solution, stopper the flask, allow it to stand one-half hour, with frequent shaking, and titrate the excess ferrous sulfate with 0.1 normal potassium permanganate solution: (The acid ferrous sulfate solution must be freshly prepared and standardized by a control titration).

Triisopropanolamine. The triisopropanolamine, $\text{N}(\text{C}_3\text{H}_7\text{OH})_3$, used in the preparation of sobisminol mass and sobisminol solution responds to the following tests for identity and purity:

Triisopropanolamine occurs as a colorless to pale yellow colored, pasty semicrystalline mass, possessing a slight characteristic odor and a bitter taste. It melts to a clear liquid at a temperature of not less than 46 C.

Triisopropanolamine is readily soluble in acetone, alcohol, ether, chloroform and water.

Dissolve 1 Gm. of triisopropanolamine in 10 cc. of water; the solution is alkaline to litmus and only very slightly turbid. Dissolve 1 Gm. of triisopropanolamine in 20 cc. of water, divide the solution into two portions; to one portion add 0.5 cc. of normal hydrochloric acid, filter, if necessary, and add to the clear filtrate 1 cc. of barium chloride solution; the other portion add 0.5 cc. of nitric acid and 1 cc. of silver nitrate solution; not more than a faint turbidity develops in five minutes (*sulfate*); to the arsenic content of triisopropanolamine is produced (*chloride*); to per million; heavy metals are absent (U. S. P. XI). Incinerate 5 Gm. of triisopropanolamine; the weight of the ash does not exceed 0.05 per cent.

Transfer about 5 Gm. of triisopropanolamine to a 100 cc. volumetric flask and assay for nitrogen as directed under sobisminol mass: the amount of nitrogen found is not less than 7.1 per cent nor more than 7.6 per cent. Dissolve about 1 Gm. of triisopropanolamine, accurately weighed, in 50 cc. of distilled water and titrate with half-normal hydrochloric acid; each cubic centimeter of which is equivalent to 0.0955 Gm. of triisopropanolamine, using methyl red as the indicator; the triisopropanolamine content should be not less than 98.5 per cent nor more than 101.5 per cent.

Sobisminol Mass-Cutter.—A brand of sobisminol mass—N. N. R.

Manufactured by Cutter Laboratories, Berkeley, Calif., by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Mass-Lilly.—A brand of sobisminol mass—N. N. R.

Manufactured by Eli Lilly and Company, Indianapolis, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Mass-Squibb.—A brand of sobisminol mass—N. N. R.

Manufactured by E. R. Squibb & Sons, New York, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Mass-Squibb.—A brand of sobisminol mass—N. N. R.

Manufactured by E. R. Squibb & Sons, New York, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Mass-Squibb Capsules: Each capsule contains 0.75 Gm. of sobisminol mass representing 150 mg. of bismuth as an organic bismuth compound obtained by the interaction of sodium bismuthate, triisopropanolamine and propylene glycol.

SOBISMINOL SOLUTION.—A solution containing a complex organic bismuth product the chemical nature of which has not been fully established. It is obtained by dissolving the products of the interaction of sodium bismuthate, triisopropanolamine and propylene glycol in a mixture of propylene glycol and water. Each cubic centimeter of the solution contains between 19.5 and 20.5 mg. of bismuth and 0.5 cc. of propylene glycol.

Actions and Uses.—Sobisminol solution is proposed in the treatment of all types of syphilis and is claimed to be free from unusual discomfort when used by the intramuscular injection route.

Dosage.—From 1 to 2 cc. intramuscularly into the muscles of the buttocks twice a week. With young children the dosage may be lowered in proportion. Generally a series of from twenty to twenty-five injections is considered a course of treatment. In cases of arsenical sensitization the bismuth injections may be continued for a much longer period.

Sobisminol solution occurs as a clear, dark brown-red colored liquid, possessing an odor similar to triisopropanolamine and a sweet, mildly metallic taste. It is miscible with an equal volume of water or alcohol. The pH of a portion of sobisminol solution is not below 11.1 nor above 11.5 as determined by means of a glass electrode. The specific gravity of sobisminol solution is not less than 1.064 nor more than 1.066 at 25 C.

Undiluted sobisminol solution responds to the tests for identity and purity stated under sobisminol mass.

Transfer 5 cc. of sobisminol solution, accurately measured, to a 500 cc. beaker and determine the bismuth content according to the method stated under sobisminol mass; the amount of bismuth found is not less than 0.0195 Gm. nor more than 0.0205 Gm. per cubic centimeter.

Transfer 5 cc. of sobisminol solution, accurately measured, to a Kjeldahl flask and determine the nitrogen content according to the method stated under sobisminol mass; the amount of nitrogen found is not less than 0.0054 Gm. nor more than 0.0060 Gm. per cubic centimeter.

The propylene glycol, sodium bismuthate and triisopropanolamine used in the preparation of sobisminol solution corresponds to the standards for these substances as indicated under sobisminol mass.

Sobisminol Solution-Cutter.—A brand of sobisminol solution—N. N. R.

Manufactured by Cutter Laboratories, Berkeley, Calif., by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Solution-Lilly.—A brand of sobisminol solution—N. N. R.

Manufactured by Eli Lilly and Company, Indianapolis, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Solution-Squibb.—A brand of sobisminol solution—N. N. R.

Manufactured by E. R. Squibb & Sons, New York, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Solution-Squibb.—A brand of sobisminol solution—N. N. R.

Manufactured by E. R. Squibb & Sons, New York, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

Sobisminol Solution-Squibb.—A brand of sobisminol solution—N. N. R.

Manufactured by E. R. Squibb & Sons, New York, by license of Stanford University under U. S. patent 2,125,561 (Aug. 2, 1938; expires 1955). No U. S. trademark.

SATURDAY, DECEMBER 16, 1939

The Platform of the American Medical Association

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

ORAL BISMUTH THERAPY IN SYPHILIS

The use of alternating courses of arsenicals, administered intravenously, with intramuscular injections of bismuth compounds in the treatment of syphilis is a standard procedure with many syphilologists. With this therapy the disease is under constant attack by the respective metallic compounds. Physicians who use the injection technic may be assured that the patient has received the prescribed dose. The routine weekly schedule facilitates the observation of the effect of the medication on the disease and on the patient. Regularity of examination and treatment is important to both the patient and the physician. It affords frequent opportunity for mental and moral influence, and encouragement by the physician. It aids in the maintenance of adequate records, which are useful in statistical evaluation of various therapeutic regimens. Perhaps most important to the individual and to society, routine administration of medication provides the physician with an effective means of insuring the prolonged cooperation of the patient—an essential requirement for the successful termination or control of the disease. Any plan of treatment which lacks these advantages requires serious consideration from a public health and socio-economic point of view before it is accepted as a suitable method for the treatment of syphilis.

Now, for the first time, appears a metallic preparation which seems to be useful when administered orally for the treatment of syphilis. The fact that it is taken orally indicates that it may frequently be adapted for self administration. This form of therapy is certainly not advisable except for intelligent, cooperative patients. Forgotten doses of medication or negligent behavior on the part of the patient must inevitably lead to relapse with consequent possibilities of infection of other people. It is essential that the patient take the medication regularly, as directed by the physician, or that the physician insist on the intramuscular route for therapy for uncooperative patients.

There are, of course, certain instances in which the oral route of medication would be a valuable adjunct in syphilis therapy. It can be used with caution for those individuals whose business or profession necessitates occasional absences from the physician's supervision. It should prove useful for those rare persons who have unusual difficulty in taking intramuscular injections because of resultant pain and induration of the muscles. It is also possible that in selected cases of congenital syphilis and in some cases of cardiovascular and latent syphilis the oral route of medication would be distinctly useful.

In the course of experiments directed toward the utilization of sodium bismuthate in antisyphilitic therapy, Hanzlik, at Stanford University, evolved preparations resulting from the interaction of sodium bismuthate, tri-isopropanolamine and propylene glycol, known as sobisminol mass and sobisminol solution. These products have been before the Council on

Pharmacy and Chemistry for approximately three years, a period which was necessary for the accumulation and proper evaluation of evidence for the efficacy of the orally administered product. Elsewhere in this issue of *THE JOURNAL* appears a statement by the Council on Pharmacy and Chemistry on sobisminol mass in capsules and sobisminol solution, and the announcement of acceptance of various marketed brands of these products. The studies of Hanzlik and his co-workers, of Sollmann, Cole and Henderson, and of others have shown, by clinical observations of antisyphilitic effects of sobisminol mass when given in sufficient dosage, that there is satisfactory absorption of bismuth following sobisminol mass by the oral route. Similarly confirmatory studies by Meininger and Barnett and by Scholtz, McEachern and Wood appear in this issue (pp. 2214-2223). Attention is directed to a rapid clinical method for quantitative determination of bismuth, devised by Hanzlik and his co-workers, which has been used effectively to maintain accurate observations of the level of bismuth excreted in the urine of patients treated with bismuth preparations. Adequate references to these studies appear in the report of the Council on Sobisminol (this issue, p. 2235). While some gastrointestinal disturbances have been encountered, generally they have not been sufficiently serious to interfere with adequate treatment.

This oral remedy cannot be expected to replace completely the carefully supervised use of other established therapeutic agents. It is to be emphasized that, while an oral bismuth preparation may in some situations be substituted in whole or in part for a bismuth preparation administered intramuscularly, it could never serve as an adequate substitute for alternate courses of arsenicals and bismuth compounds.

Sobisminol mass must not be sold over the counter to the public as a cure for syphilis. If it were thus marketed, the product would be a real danger and detriment to the public health. Both Hanzlik and the manufacturers are most anxious that no such contingency shall arise. Therefore, according to agreements between the board of trustees of Stanford University and each of the three firms already licensed to manufacture the product, every legal effort is being made to prevent the sale of capsules of sobisminol mass to the public other than on or by the prescription of the physician. Self medication in acute syphilis can only lead to relapse and resultant danger to the public health.

The ultimate evaluation of the therapeutic efficacy of a new drug such as sobisminol mass necessarily requires a long time. The close cooperation of Hanzlik and other investigators, the manufacturers, the Food and Drug Administration and the Council on Pharmacy and Chemistry in careful studies designed to evaluate and control this new product properly is highly commendable.

To summarize: A new antisyphilitic agent with the special property of effective oral administration will

soon be taking its place in the alleviation of the ravages of syphilis. Physicians, pharmacists and public health authorities must take care that sobisminol mass is not supplied directly to the public. Such distribution would obviously result in inadequate treatment of unrecorded and uncontrolled cases and thus would become a serious menace both to the individual and to the public health. Lastly it is pointed out that oral administration of bismuth compounds is not intended to replace the generally accepted use of bismuth preparations intramuscularly, except where special conditions prevail.

COLLAPSE THERAPY FOR PULMONARY TUBERCULOSIS AS A PUBLIC HEALTH MEASURE

Since the late Theodore B. Sachs called attention to the menace of the wide spread of tuberculosis in Chicago, the isolation of patients with the disease in the open, or contagious, stage has come to be considered the important feature in the campaign against this disease. Isolation of patients with tuberculosis in a contagious form from children under 16 years of age was made mandatory in 1917. Despite the energetic and even rigorous enforcement of the law, the number of uncontrolled cases of tuberculosis in the community was not decreased. Hruby¹ stated that in 1931 there were 700 patients on the waiting list of the Municipal Tuberculosis Sanitarium and as many on the waiting lists of the Cook County Hospital and Oak Forest institution. There were 20,000 registered cases in Chicago but only 2,471 available beds. While the idea of isolating patients with open tuberculosis was correct, it failed in its practical application for the simple reason that there was no place for the isolated persons to go.

In 1931 the board of the Municipal Tuberculosis Sanitarium initiated a program of collapse therapy on a mass scale in an attempt to stem the sources of infection. Every suitable patient at the institution and in the field was to receive the benefits of collapse therapy. The results of the campaign have now been analyzed. Of 7,344 patients treated during the period between 1931 and 1936, 3,090 were treated by the induction and maintenance of pneumothorax for more than three months, while 3,584 patients were treated without collapse therapy. Of the 3,090 patients treated, 94.2 per cent had advanced tuberculosis, 84.4 per cent had positive sputum and 81.3 per cent had cavities. Of the total, 14.2 per cent were Negroes. In the collapse group 53.9 per cent were converted from positive sputum to negative, while in the control group the conversion amounted to 15.3 per cent. Thus, since the inception of the program, according to Hruby, 1,285 "fountains of infection" have been shut off. After the treatment 64.3 per cent are still living, as compared with 31.3 per cent in the control group. Of 1,215

1. Hruby, Allan J.: Collapse Therapy of Tuberculosis Seen from the Viewpoint of Control of the Disease in the Community, *Am. Rev. Tuberc.* 40: 255 (Sept.) 1939.

patients with positive sputum converted to negative, 227 had been negative from two to three years, 154 for from three to four years, ninety-four for from four to five years, twenty-seven for from five to six years, and twenty-five for six years and over. While the mortality rates for the Municipal Tuberculosis Sanitarium based on a study of 8,779 cases amounted to 82.96 per cent for a five year period and 91.16 per cent for the ten year period, the group in which collapse therapy was practiced showed a survival rate of 69.3 per cent at the end of five years.

Extensive collapse therapy justified itself from the point of view of protecting the community, because it converted a relatively large number of open cases, for which hospitalization facilities did not exist, from a positive to a negative sputum. To overstress the importance of the widest possible collapse program and at the same time to understress or to leave unemphasized the much greater importance of creating facilities for the immediate hospitalization of the tuberculous would be wrong. A more correct orientation toward the pneumothorax therapy would be to regard it as a problem of the individual rather than as a public health measure. Indirectly of course the public would benefit as well. In every urban community there are many persons with unrecognized open tuberculosis. Cases are diagnosed as a rule in the advanced stage of the disease, that is, after countless numbers of others have been exposed to infection. Not all the cases are suitable for collapse therapy and the latter is effective in only a certain proportion. Pneumothorax therapy cannot therefore be regarded as more than a significant aid in the wider problem of the eradication of tuberculosis. The control of this condition is largely a matter of early diagnosis and segregation. No doubt the program would have yielded still better results in Chicago if better facilities for applying the principle of segregation had been available.

Current Comment

PRURITUS OF THE ANUS AND VULVA

Medical literature contains a variety of opinions concerning the cause and treatment of pruritus of the anus and vulva. Recently the Haileys¹ stated that the majority of cases of essential, idiopathic or true pruritus of the anus and vulva are due to eczema, the causes of which are essentially the same as those causing eczema in other anatomic localities. The patient's heredity makes a suitable soil for the development of the eczema, as it does for the development of asthma, hay fever, urticaria and migraine in hypersensitive persons. Pruritus of the anus and vulva, in fact, is eczema of those regions and as such is a manifestation of hypersensitiveness in the skin. The direct causes which bring on the attacks may be chemical substances, including some drugs and dyes, clothing, including wool; rubber and some synthetic fabrics, hemorrhoids, diet, heat,

atmospheric conditions or perspiration and friction. The Georgia investigators believe that, if it were always possible to obtain a reliable history, almost every case would give a history of hypersensitiveness in the family. In their series of 105 cases, more than 60 per cent gave such a history of manifestations of hypersensitiveness. Benefit in the way of treatment was offered by the roentgen ray. They obtained clinical cures lasting from months to years in 80 per cent of their cases and improvement in an additional 15 per cent. One should insist, however, on having an accurate record of any previous roentgen treatment in order to avoid possible unfortunate sequelae.

THE ONE HUNDRED AND FIFTIETH ANNIVERSARY OF THE MEDICAL SOCIETY OF SOUTH CAROLINA

At special ceremonies December 5 the Medical Society of South Carolina celebrated its one hundred and fiftieth anniversary. The governor of South Carolina, the mayor of Charleston, the present and retiring presidents of the South Carolina Medical Association, representatives of each county medical society in the state and many others were invited. Dr. Nathan B. Van Etten, New York, President-Elect of the American Medical Association, and Dr. Francis R. Packard, Philadelphia, editor of the *Annals of Medical History*, gave addresses. Dr. James J. Ravenel, president of the Medical Society of South Carolina, gave a historical sketch of the society. Dr. William Weston, Columbia, S. C., presented a tablet from the South Carolina Medical Association, signifying the cordial relation that has existed between the two organizations throughout the history of the state society; especially strong ties between the two organizations have been a mutual interest in medical education and the support of the Medical College of the State of South Carolina. An additional indication of cooperation is the dedication of the current issue of the *Journal of the South Carolina Medical Association* to the Medical Society of South Carolina. This was the only medical organization in South Carolina until 1848, when this society called a convention which formed the South Carolina Medical Association. Although retaining its original name, the older society then became a constituent member of the state association. Dr. James Moultrie was elected president of the new state organization and three years later, when the American Medical Association held its annual meeting in Charleston, he was elected president of the national organization. The Medical Society of South Carolina has taken great interest in promoting public health in its own community. For years it also recorded observations on the weather and conducted a botanic garden as a scientific exhibit; a medical college was established under its auspices more than a hundred years ago. Its members have made many contributions to medicine. It has a collection of books which go back to the day of its birth, including one containing the original minutes of the organization in which new members today still sign their names. The Medical Society of South Carolina is the fourth oldest medical society in the United States, almost as old as the United States government itself.

ORGANIZATION SECTION

PROPOSED PROCEDURES OF UNITED STATES CHILDREN'S BUREAU

A meeting of the Committee on Maternal and Child Health of the State and Territorial Health Officers, together with certain representatives of the Children's Bureau advisory committees on maternal and child health, was held at the Children's Bureau, September 9.

The meeting was called to consider problems connected with the increased appropriations for 1940 for maternal and child health as authorized in the amendment to the Social Security Act approved August 10. The meeting had to do with methods rather than policies.

Following are excerpts from a report on the meeting submitted under date of November 14 by the United States Children's Bureau at the request of THE JOURNAL:

A. It is recommended that the additional federal maternal and child health funds should be used (1) to improve quality of services now under way, (2) to extend specific maternal and child health services or (3) to establish demonstrations of types of service needed to enlarge the scope of care and to provide programs of complete maternity care and care of children.

B. It is further recommended that a portion of the additional federal appropriations for fund B be set aside for providing medical, nursing and hospital care for maternity patients and children in selected areas.

C. It is recommended that the use of the new federal funds be limited to one or more of the following types of service:

I. EXPANSION OF ESTABLISHED MATERNAL AND CHILD HEALTH PROGRAMS WITH OPPORTUNITY FOR ADDITIONAL FEATURES

1. Types of Medical Services—

Personnel: (a) Full-time pediatricians or obstetricians on state or local staff to assist in administration, conduct or supervision of medical aspects of program.

(b) Full-time or part-time pediatricians or obstetricians to provide clinical case consultation or to supervise newly organized outpatient clinics in pediatrics or obstetrics.

(c) Qualified local practicing physicians on part-time or fee basis to provide medical care for maternity patients or for infants and children.

(d) Other specialists (medical or surgical) as requested by attending pediatrician or obstetrician on part-time or fee basis.

Clinical services: (a) Extension of antepartum or child health clinics or conferences.

(b) Outpatient clinics in pediatrics or obstetrics, associated with public or nonprofit hospitals, in communities without such clinic services.

(c) Hospital or home care for maternity cases or for sick children.

2. Types of Nursing Services—

(a) Maternal and child health nursing consultants or supervisors on state or local staffs to assist in administration and supervision of the obstetric and pediatric nursing aspects of the maternal and child health services.

(b) Additional qualified public health staff nurses to render generalized public health nursing services which include maternal and child health services, and bedside care of maternity patients and sick children.

(c) Bedside nursing service for maternity cases or sick children on case basis by qualified registered nurses under supervision of public health nurses.

3. Other Services—

(a) Nutritionists on state or local staff to develop nutrition service in the maternal and child health program.

(b) Medical social workers on state staffs in connection with medical care programs for maternity patients or children.

4. Postgraduate Education—

(a) In medical centers—clinical courses in pediatrics or obstetrics for general practitioners.

(b) Lectures and clinics in communities throughout the states.

(c) Postgraduate education and training in pediatrics and obstetrics for full-time medical and nursing or other maternal and child health staff of state or local health agencies.

5. Regulation and Supervision of Maternity Hospitals or Homes.

Recommendations were also made regarding special demonstrations of medical care in maternity or childhood as required by the Social Security Act. These recommendations covered "maternity care and care of newborn infants including program of medical, nursing and hospital care in selected areas, providing payment for care by qualified physicians and nurses at home or in qualified hospitals." Detailed recommendations were made for carrying out these demonstrations. Among these were recommendations that diagnostic and treatment centers were to be organized in suitable hospitals, preference to be given to public hospitals where practicable. A technical advisory committee was recommended in each state to consist of obstetricians and pediatricians, including the chairman of the committee on maternal welfare of the state medical society or other physician designated by the society; the state chairman for the American Academy of Pediatrics and a local practitioner from a small community or rural area, with such other members as the state health department may wish to appoint. All procedures must be according to minimum *Federal Standards* (italics in original), and a detailed descriptive plan for the work must be submitted by the state health department to the Children's Bureau. Extensive requirements for hospitals providing care for maternity patients and newborn infants when such care is paid for from federal maternal and child health funds are outlined. Many of these are already included in the standards of the Council on Medical Education and Hospitals of the American Medical Association and of the American College of Surgeons.

Among other provisions is one to the effect that when maternal or child health care is paid for from federal funds "consultation with specialist in obstetrics" shall be "required prior to any major obstetric operation (mid and high forceps, breech extraction, version, cesarean section, mutilating operations) and for the treatment of serious complications such as eclampsia, placenta praevia, abruptio placentae, unless serious hemorrhage will not permit time to call consultant."

Provisional standards for diagnostic and treatment centers for children in a small city were set up along lines parallel to the maternal care demonstration standards, with preference again given to public hospitals where practicable and with a technical advisory committee of similar composition except that pediatric medical interests instead of obstetric are included.

The agenda for the committee meeting included a discussion of the merit system provided in the Social Security Act, title V, parts 1 and 2 as amended Aug. 10, 1939, which says:

"Clause (3) of Section 503 (a) (and of Section 513 (a)) of such act is amended to read as follows: '(3) provide such methods of administration (including after January 1, 1940, methods relating to the establishment and maintenance of personnel standards on a merit basis, except that the Board shall exercise no authority with respect to the selection, tenure of office, and compensation of any individual employed in accordance with such methods) as are necessary for the proper and efficient operation of the plan.'"¹ Although this merit system was mentioned several times during the meeting there was no genuine discussion of it nor were the details presented to the committee. It is outlined in a circular² now issued by the United States Children's Bureau. This circular incorporates the recommendations of the advisory committees briefed in the foregoing and discussions of jurisdiction under the merit system as applied to state employees and local employees; to all intents and purpose it means that any employee in a project carried out with federal funds or with the assistance of federal funds under title V of the Social Security Act will be required to be under the merit system. Exemptions are members of state and local boards or commissions, executive heads of state agencies administering functions provided under title V of the Social Security Act, members of advisory councils, committees or similar bodies paid only for

attendance at meetings, and state and local officials serving ex officio or performing incidental duties to such plans. State civil service systems are recognized and cooperation with them is contemplated. There are provisions against discrimination because of an applicant's political or religious opinions. Limitation of political activity is required and classification plan and compensation plans are required.

Permanent employees who have acquired permanent status under a state civil service or merit system established by law do not come under the Social Security Act merit system, but those who have not acquired permanent status but have served satisfactorily may be admitted either to an open competitive examination or to a qualifying examination. Detailed rules are outlined for the recruitment and appointment of new personnel, for registers of eligibles, provisions for making provisional appointments for probationary periods, promotions, furloughs, service ratings and personnel records.

Officers and committee members of state medical societies functioning in cooperation with a state department of health or other state agency operating in conjunction with title V of the Social Security Act should seek for more detailed information relative to these projects from the state board of health. The initiation of state plans is the responsibility of the state health officer. The advisory committees provided include representation of state medical societies in order that the advice of the medical profession in the several states may be available to state health departments through officially constituted channels.

STATE EDUCATION AND STATE MEDICINE

A STATEMENT BY THE BUREAU OF MEDICAL ECONOMICS

The state maintains a system of education; why should it not maintain a system of medical care? It protects us against invasion, why not against disease? This is a frequent argument for state medicine. Analogy is proverbially a dangerous foundation for a logical premise. Although most persons are exposed to both disease and education, many persons fail to get either.

In childhood and youth every one needs much the same sort of education. Health and illnesses are as individual as human beings. In adult life there are many who wish to learn the same things, so that books, lectures, classes and the radio can be used effectively for mass treatment of their educational needs. Mass diagnosis and treatment of illness breed disaster! Fairly accurate diagnoses of ignorance and of progress through educational treatment may be made by mass examinations, although even in education there are some doubts as to the accuracy and efficiency of such mass methods.

Ignorance does not appear suddenly or in epidemic form nor does it create an emergency demand for education. The need for education varies only slightly with times and conditions. The positive benefits of education are not confined to the individual. Society realizes a direct return on its investment in the education of its members.

Health and ignorance are alike only in a few features and within those limits the state is already active in both fields. The value of that state activity depends largely on how closely it is limited to the fields for which it is fitted. Whatever can be done for the people as a whole represents activities in which the state may properly concern itself. Where individuals must be distinguished and given widely different and appropriately individualized treatment the mass action of government is seldom successful.

The state can establish quarantine to protect all the people against the invasion of disease; it can collect and tabulate vital statistics pertaining to the whole population; it can assist in health education, urge widespread general immunization and rally the forces to meet the mass attacks of epidemics. Within these and such other limits as have the same qualities and objectives the medical profession has always aided and encouraged state activity.

When individuals are to be aided in the recovery from illness, the analogy of disease with education becomes a contrast. It is seldom that two persons need exactly the same medical care. The nature and

1. Recommended Standards for the Establishment of a Merit System of Personnel Administration and for Qualifications of Certain Classes of Professional Employees in State and Local Agencies Administering Maternal and Child Health Services, Services for Crippled Children, or Child Welfare Services, Under the Social Security Act, Title V, Parts 1, 2 and 3, as amended, Special Information Circular No. 1, U. S. Children's Bureau, Washington, D. C., November 1939.

2. Recommended Standards for the Establishment and Maintenance of a Merit System of Personnel Administration and for Qualifications of Certain Classes of Professional Employees in State and Local Agencies Administering Maternal and Child Health Services, Services for Crippled Children, or Child Welfare Services Under the Social Security Act, Title V, Parts 1, 2 and 3, as amended, Special Information Circular No. 1, U. S. Department of Labor, Children's Bureau, Washington, D. C., Nov. 1, 1939.

degree of illness and the progress of recovery vary widely; moreover, diseases and sick persons cannot be standardized according to the grades as used in the educational system.

Medical service does not fit into time tables or arbitrarily prepared curriculums. It is largely a twenty-four hour service. Its value depends largely on a personal relation between two individuals—the patient and the physician. It must be given at widely varying intervals to each individual who needs and desires the service, and its value depends to a high degree on the way it is suited to each personal requirement.

The reasoning which would have medicine follow the pattern of education is further weakened by an increasing volume of evidence that standardization in education has not been wholly successful. Forcing teachers and pupils into a common mold is held to be destructive of both individual and social values. Such standardization injures those of exceptional ability and thereby deprives the nation of greatly needed intelligent, independent leadership.

The universal and well-nigh equal need for education has not, under governmental control, kept its distribution, both as to quantity and quality, from varying widely in different localities. In spite of the more uniform character of education compared with medical care, few would claim that our educational system is efficiently administered. The thousands of one room schools, of underpaid and poorly trained teachers, and the failure, shown by numerous surveys, of some whole state systems to produce any satisfactory educational results do not encourage application of the same methods to the far more complex problems of personal medical care.

Political influence and pressure groups have worked much harm to education, although it is much better suited to resist or endure such influences than medical

service. It is charged that lay supervisors, ignorant of pedagogic methods, hinder professional progress and tend to cripple the freedom of thought and investigation that is of fundamental importance in education. Such influences would be much more destructive in the medical field.

In spite of the fact that education is freely offered by the state to every one and that more than 26,000,000 pupils were in elementary and high schools in 1931-1932, there were at the same time more than 2,700,000 in private and parochial schools. In other words, 10 per cent of the population refused to accept the standardized system for which they had already paid through taxation and preferred to pay a second time for the kind of education they considered more suitable to their individual desires.

The total cost of public day schools amounted to over \$2,160,000,000 and the expenditures in universities and colleges was over \$600,000,000 more. It was impossible even with these great expenditures and the enormous extent of standardization to provide employment for those who had been accepted as teachers.

In 1936 the Works Progress Administration reported that in January of that year there were 1,218 "physicians, surgeons and dentists" and 40,132 teachers who had been declared eligible for works program employment with the WPA. The effect of the depression was a widespread reduction in educational services and failure to pay those teachers who still remained at their work.

By just so much as education does resemble medical service it seems to have suffered under state administration. Only where the contrast is greatest has it been successful. If a comparison is to be made it would seem to be rather as a warning than as an example.

OFFICIAL NOTES

THE NEW YORK SESSION

Chairman of the Local Committee on Arrangements

Dr. Charles Gordon Heyd, New York, will serve as chairman of the Local Committee on Arrangements for the New York Session, which will be held June 10-14, 1940.

Applications for Reservations to the Subcommittee on Hotels

The Subcommittee on Hotels of the Local Committee on Arrangements has furnished a list of New York hotels and rates for rooms, which can be found on advertising page 32 of this issue of *THE JOURNAL* together with an application form that may be used to secure reservations through the Subcommittee on Hotels.

The form printed in the advertising pages may be clipped and, when it has been properly filled in, should be sent at once to Dr. Peter Irving, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, Room 1036, 233 Broadway, New York.

If those who expect to attend the annual session of the American Medical Association will send in their applications at the earliest possible time, there should be no difficulty encountered in securing satisfactory accommodations. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference. It will greatly expedite matters if requests for reservations are addressed directly to Dr. Irving.

RADIO BROADCASTS

The seventh season of broadcasting by the American Medical Association over the facilities of the National Broadcasting Company and affiliated stations is now under way with programs scheduled each Thursday at 4:30 p. m. eastern standard time (3:30 central standard time, 2:30 mountain time and 1:30 Pacific time). The program is on the Blue network of the National Broadcasting Company, the key station of which is WJZ, New York.

It is impossible to publish a list of topics in advance when programs are developed from last minute proof of pages of *THE JOURNAL*. It is possible to say that future programs under consideration involve one each dealing with progress in medicine, rabies, infantile paralysis, maternal and child health, hospitals, medical education and industrial health. These programs will be as appropriate as possible to the season at which greatest interest in these topics is manifested. The programs on hospitals, medical education and industrial health will correspond with publication dates of special issues of *THE JOURNAL* devoted to these topics. The program on medical progress will be broadcast December 28. The programs on maternal and child health will be a part of the spring series.

A special program in cooperation with the National Foundation for Infantile Paralysis, Inc., and the Committee for the Celebration of the President's Birthday is scheduled to appear as the regular program dated January 11.

Lists of radio stations which have signified their intention of broadcasting Medicine in the News, according to information received from the National Broadcasting Company, were published in *THE JOURNAL* December 2, page 2065.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

Annual Registration Due January 1.—Every person practicing medicine, surgery or osteopathy in Arizona is required by law to pay annually on or before January 1, to the board of medical examiners, a renewal license fee of \$3. Any licensee who does not renew his license as required above is to be penalized \$1 for each day that he practices without a renewal license, not to exceed \$50. The board of medical examiners is to revoke the license of any licensee who fails to renew his license for three successive years.

ARKANSAS

Changes in Health Officers.—Dr. Ulys Jackson, formerly of Marshall, has been assigned as health officer of Boone County with headquarters in Harrison. Dr. James F. Hays, formerly of Augusta, health officer of Woodruff County, has been placed in charge of the health unit in Pope County with headquarters in Russellville. Dr. Alvie B. Tate, Russellville, health officer in Pope County, will go to Woodruff County. Dr. Walter W. Brown, Hardy, has been appointed health officer of Sharp County.

Annual Registration Due January 1.—Every licensee of the Arkansas Eclectic Medical Examining Board must register annually with the secretary of the board between January 1 and the last day in February and pay a fee, if a resident of Arkansas, of \$2 and, if a nonresident, of \$4. The failure of a licensee to pay the required fee by March 1 automatically suspends his right to practice while delinquent. If he fails for three successive years to pay the required fee, his license is to be canceled, and thereafter he will be reinstated only on such a showing to the board of moral character and professional qualifications as would entitle the applicant to the issuance of an original license and the payment of the same fee as is required for the issuance of an original license.

Society News.—At a meeting of the Washington County Medical Society November 7 a symposium on thyrotoxicosis was presented by Drs. Arless A. Blair, Arthur F. Hoge and William R. Brooksher, all of Fort Smith. The speakers before the Mississippi County Medical Society November 7 were Drs. Henry B. Gotten and Charles G. Andrews, both of Memphis, Tenn., on "Acute Nephritis" and "Salivary Gland Tumors" respectively. At a meeting of the Benton County Medical Society in Siloam Springs November 9 Drs. George A. Hughes, Siloam Springs, spoke on "Vaginal Hysterectomy" and Harry L. Deutsch, Stilwell, Okla., "Infectious Mononucleosis." Dr. Pat Murphey, Little Rock, addressed the Pulaski County Medical Society November 20 on "Use of Air in the Treatment of Spastic Paralysis."

CALIFORNIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$2. Failure to pay the required fee within sixty days after January 1 works a revocation of a license, and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

Society News.—The San Francisco County Medical Society, the Bar Association of San Francisco and the San Francisco District Dental Society held a joint dinner meeting December 7. Dr. Vernon P. Thompson, Los Angeles, discussed backache before the San Diego County Medical Society December 12. At a joint meeting of the staff of Mercy Hospital, San Diego, and the San Diego Academy of Medicine December 6 Dr. A. Graeme Mitchell, Cincinnati, discussed "Medical Caricatures."

New Building for Research at Stanford.—A new building for research has been opened at Stanford University School of Medicine, San Francisco, the gift of Mrs. Louis Stern, Palo Alto. Costing about \$97,000, the Ruth Lucie Stern Research

Laboratory is three stories high, providing more than 6,000 square feet of laboratory space, all of which is exposed to direct outside light. The second floor is occupied by research in pediatrics and the top floor by the gynecologic pathologic section, female endocrine studies and cancer research.

CONNECTICUT

Society News.—The Yale Medical Society was addressed December 13 in New Haven, among others, by Drs. John R. Paul and James D. Trask on "Familial Epidemiology in Poliomyelitis." Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, will address the midwinter dinner of the Connecticut State Medical Society January 25 on "American Medicine and the National Government."

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January with the state department of health and at that time to pay a fee of \$2. Licensees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

FLORIDA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1 with the secretary of the state board of health and at that time to pay a fee of \$1. A licensee failing to register annually is liable to a fine of not more than \$50.

District Meetings.—At a meeting of the Second District Medical Society in Quincy October 19 the speakers included Drs. Arthur J. Logie, Jacksonville, on "Recent Advances in Tuberculosis"; Frank M. Hewson Jr., Chattahoochee, "Modern Conception of Epilepsy," and Helen W. Bellhouse, Thomasville, Ga., "Undulant Fever in Children: Its Diagnosis and a Report on Two Cases." The third annual meeting of the South Central Medical District Society was held at Sanford November 2. Among the speakers were Drs. George R. Crisler, Winter Park, on "The Efficacy of Anterior Pituitary Growth Principle in a Diabetic"; Clyde F. Bowie, Leesburg, "Kidney Infection as a Result of Obstruction"; Don D. C. C. Robertson, Orlando, "Inguinal Hernia," and Rollin D. Thompson, Orlando, "A Résumé of the First Year's Work at the State Sanatorium."

ILLINOIS

North Central Illinois Medical Meeting.—The sixty-sixth annual meeting of the North Central Illinois Medical Society was held in Bloomington December 12. The speakers included:

Dr. Benjamin Markowitz, Bloomington, Jaundice Types.
Dr. Emil D. W. Hauser, Chicago, Problems of the Foot.
Dr. Milton G. Bohrod, Peoria, Biopsy of Lymph Nodes for Diagnosis.
Dr. Aaron Arkin, Chicago, Blood Dyscrasias.
Dr. LeRoy H. Sloan, Chicago, Neurologic Problems.
Dr. James Herbert Mitchell, Chicago, Differential Diagnosis of Cutaneous and Mucous Membrane Syphilis.
Dr. Norris J. Hecker, Chicago, Newer Advances in the Treatment of Infections of the Genito-Urinary Tract.
Dr. Edwin M. Miller, Chicago, Fractures About the Elbow.
Dr. Warren H. Cole, Chicago, Surgical Aspects of Diseases of the Pancreas.
Dr. M. Herbert Barker, Chicago, Hypertension.

Drs. Robert S. Berghoff and Donald A. Hirsch, both of Chicago, conducted a heart clinic.

Chicago

Personal.—Dr. Max Thorek, Chicago, was recently made a commander of the Order of St. Alexander of Sofia for his contributions to surgical science. The honor was conferred during the fiftieth anniversary of the founding of the University of Sofia, Bulgaria.

Millions for Research.—Northwestern University will receive \$1,500,000 and the University of Chicago \$1,000,000 under the will of the late Mrs. Clara A. Abbott, widow of Dr. Wallace C. Abbott, founder of the Abbott Laboratories in North Chicago. The money in both instances is to be used for medical, surgical or chemical research. It was announced that the Physiological Building at the University of Chicago would be renamed Abbott Memorial Building, while Northwestern plans to give the name of Abbott Hall to the eighteen story dormitory which is being erected on the Chicago campus. The bequest to the University of Chicago assures an additional grant of \$1,500,000 to the university from the

Rockefeller Foundation, which in 1938 offered the grant for research in the biologic sciences on condition that the university obtain an additional \$500,000 by 1941.

Society News.—The Chicago Society of Internal Medicine was addressed November 27 by Drs. Michael H. Streicher on "Appendicitis—Incidence of Amebiasis in a Clinical Review of 3,407 Cases"; Ralph B. Bettman and Gemma M. Lichtenstein, "Acute Cholecystitis," and Laurence E. Hines, Allen H. Hoover and Edwin Graff, "Effect of Sulfanilamide on the Fibrinolytic Activity of Hemolytic Streptococci."—A symposium on hydronephrosis was presented before the Chicago Council of Medical Women November 8 by Drs. Elizabeth Rothfus Fischer, Elizabeth Clancy, Marie Ortmyer, Lillian Eichelberger and Eleanor M. Humphreys.—The Chicago Ophthalmological Society will be addressed December 18 by Mr. Hugh Hunter, among others, on "Optical Considerations of Contact Lens Prescriptions."—The Chicago Society of Contactology of Hyperergic Inflammation.—The speakers before the Chicago Pediatric Society December 19 will be Drs. Philip L. Aries on "An X-Ray Study of the Osseous Development in the Newborn with Special Reference to Congenital Syphilis" and Ernst Gellhorn, "Clinical Implications of Recent Studies on Anoxia and Asphyxia."

LOUISIANA

Annual Renewal Due January 1.—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually on or before January 1 by the secretary-treasurer of the state board of medical examiners and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

MASSACHUSETTS

Society News.—Among the speakers before the Massachusetts Tuberculosis League November 13 was Dr. Esmond R. Long, Philadelphia, on the uncompliant tuberculosis patient.—Dr. Howard M. Clute, Boston, addressed the Boston Gastroenterological Society November 8 on "Cancer of the Stomach."—At a meeting of the Boston Infectious Disease Society November 2 Drs. William M. Hammon spoke on "Panleukopenia of Cats: A Virus Disease"; William A. Davis, "Observations on the Role of Birds and Mosquitoes in the Spread of Equine Encephalomyelitis," and John R. Mote, "Experiments with Haemophilus Influenzae (Human) in Swine."

District Meetings.—At a meeting of the Suffolk District Medical Society in Boston November 29 Drs. William Leifer, Louis Chargin and Harold T. Hyman, New York, discussed "The Theory and Practice of Massive Dose Chemotherapy by the Intravenous Drip Method in the Treatment of Early Syphilis."—The Norfolk District Medical Society devoted its meeting in Boston November 28 to a symposium on the work of certain committees of the state medical societies with the following speakers: Drs. Robert L. DeNormandie, Boston; Michael A. Tighe, Lowell, and Charles C. Lund, Boston.—At a meeting of the Worcester District Medical Society in Grafton November 8 Dr. Charles H. Lawrence, Boston, discussed "Some Practical Uses of Endocrine Therapy" and Dr. Benjamin Cohen, North Grafton, "Comparative Effects of Phenobarbital, Dilantin Sodium and Synergistic Drug Combinations in the Treatment of Epilepsy."—John Howard Mueller, Ph.D., addressed the Middlesex South District Medical Society in Cambridge November 8 on "The Physical and Chemical Properties of Filtrable Viruses."

MINNESOTA

The Bell Lecture.—Dr. Frederick T. Lord, clinical professor of medicine emeritus, Harvard Medical School, Boston, delivered the fifth annual John W. Bell Tuberculosis Lecture before the Hennepin County Medical Society, Minneapolis, December 4. His subject was "The Clinical Aspects and Diagnosis of Pulmonary Lesions."

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January with the secretary of the board of medical examiners and at that time to pay a fee of \$2. A licensee who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

Rochester's St. Mary's Hospital Observes Anniversary.—The fiftieth anniversary of the founding of St. Mary's Hospital, Rochester, was celebrated October 27. Among the speakers were Gov. Harold E. Stassen; Dr. Donald Guthrie, Sayre, Pa.; Rev. George Philip Sheridan, D.D., Rochester, "The Hospital and Community Service"; Rev. Alphonse M. Schwitalla, S.J., St. Louis, "Principles of Good Hospital Practice"; Dr. Louis B. Wilson, Rochester, "The Pioneer Sisters," and the Most Rev. John G. Murray, D.D., archbishop of St. Paul, "The Hospital of Tomorrow." The hospital is under the care of the Sisters of Saint Francis of the Congregation of Our Lady of Lourdes. The original building was opened Sept. 30, 1889. Dr. William J. Mayo, assisted by Dr. Charles, performed the first operation, and their father administered the anesthetic. The building was three stories high with a capacity of thirty-three beds. The hospital now has a capacity of 621 beds as compared with 300 at the time it was completely rebuilt in 1922. One feature of the ceremonies held to commemorate the founding of the hospital was the breaking of ground September 30 for a new medical unit, which, when completed, will contain 445 beds and cost more than \$1,250,000.

MISSISSIPPI

New Building for Health Unit.—A new building for the Lauderdale County Health Department was recently dedicated in Meridian. Costing more than \$50,000, the unit was provided through the cooperation of the Commonwealth Fund of New York, the Mississippi State Board of Health, the city of Meridian and Lauderdale County. It will serve as a public health personnel training center. Dr. Norris C. Knight is director of the county health department.

Course in Urology.—The Southeastern branch of the American Urological Association held its sixth annual meeting at Biloxi December 8-9. With its program designed to serve as a postgraduate course for the general practitioner, the speakers included:

Dr. Roy B. Henline, New York, Prostatic Calculi.
Dr. Rubin Flocks, Iowa City, Urinary Calculi.
Dr. Charles M. McKenna, Chicago, The Correction of Some Anomalies of the Genito-Urinary Tract in Children with Special Reference to the Transplantation of the Ureter into the Large Bowel for Bladder Exstrophy.
Dr. E. Granville Crabtree, Boston, Hypertension in Relation to Kidney Disease.
Dr. Edward N. Cook, Rochester, Minn., Urinary Infections.
Col. James E. Ash, Washington, D. C., Bladder Tumors.
Dr. George R. Livermore, Memphis, Tenn., Carbuncle of the Kidney.
Dr. Edgar Burns, New Orleans, Prostatic Obstruction in Negroes.

NEBRASKA

Personal.—Dr. Charles C. Snowden, Davenport, was honored November 9 by a "Pioneer Day" sponsored by the Woman's Club of Davenport. Dr. Snowden has practiced in Davenport fifty-seven years and is still active at the age of 84. A dinner at noon was attended by more than 200 persons and a formal program in the afternoon by about 350. The Rev. A. A. Brooks, Omaha, made the principal address.—Dr. Rev. S. Pinto, Omaha, has been appointed health officer of Omaha to succeed Dr. Floyd H. Kinyoun, who resigned.

Society News.—Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, addressed the Omaha-Douglas County Medical Society, Omaha, November 28 on "American Medicine and the National Government."—At a meeting of the Five County Medical Society in Wayne November 6 the speakers were Drs. William R. Hamsa, Omaha, on "Examination and Treatment of Common Back Injuries"; Payson S. Adams, Omaha, "Treatment of Urinary Infections and the Importance of Good Drainage," and Mr. M. C. Smith, Lincoln, executive secretary of the Nebraska State Medical Association, business administration of the association.

NEW JERSEY

Society News.—Dr. Terry M. Townsend, New York, addressed the Essex County Medical Society, Newark, December 14 on "Ballots, Bullets and Bacteria."—Drs. John Russell Twiss and Rupert Franklin Carter, New York, addressed the Bergen County Medical Society, Englewood, November 14 on "Diagnosis and Medical Treatment of Gallbladder Disease."—Dr. Lester J. Unger, New York, addressed the Atlantic County Medical Society, Atlantic City, November 10 on "Value of Transfused Whole Blood, Citrated Blood and Preserved Blood."

MEDICAL NEWS

NEW YORK

Annual Registration Due January 1.—Every practitioner of medicine and surgery in New York is required by law to apply annually on or before January 1 to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives, to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

New York City

Personal.—Dr. Marion B. Sulzberger gave a series of lectures at the American Institute, November 14, 21 and 28 on "Allergy—A Fundamental Biologic Principle."—Dr. Alexander W. Kruger, deputy medical superintendent of Kings County Hospital, Brooklyn, has been named medical superintendent of Greenpoint Hospital, Brooklyn.

Third Harvey Lecture.—Karl F. Meyer, Ph.D., director of the Hooper Foundation for Medical Research and professor of bacteriology, University of California, will deliver the third Harvey Lecture of the current series at the New York Academy of Medicine December 21. His subject will be "The Host-Parasite Relationship with Particular Reference to Helicobacterium Pylori."

"Hibernation" Therapy at City Hospital.—A special chamber has been installed at City Hospital on Welfare Island to provide facilities for experiments in cryotherapy, popularly known as the "hibernation" or "frozen sleep" method of treating cancer. The room has been made possible by a donation from Mr. and Mrs. Walter C. Baker, New York. The work at City Hospital will be under the direction of a committee consisting of Drs. William Laurence Whittemore, Paul K. Sauer and James R. Lisa. Previous experimental work with this therapy has been carried on at Temple University in Philadelphia.

Directory of Tuberculosis Clinics.—The New York Tuberculosis and Health Association has published a new directory of the city's tuberculosis clinics. It lists the chief physician, social worker and supervising nurse affiliated with each clinic and quotes the hours the various clinics are at the public's disposal. The city is served by twenty-five district clinics. Nineteen are operated by the department of health, four by the department of hospitals and twenty-three conduct separate sessions for children. Pneumothorax services are available in fourteen. Thirteen consultation clinics are listed, ten operated by the health department and three by the Queensboro Tuberculosis and Health Association. The health department also has a clinic in Lower Harlem conducted as a WPA project for case finding purposes. Copies of the directory may be obtained from the association, 386 Fourth Avenue.

NORTH CAROLINA

State Society to Publish Journal.—The North Carolina Medical Society will begin publication of its own official journal in January with Dr. Wingate M. Johnson, Winston-Salem, as editor. Dr. Thomas W. M. Long, Roanoke Rapids, secretary of the state society, will be the business manager. The journal will be called *North Carolina Medical Journal*.

Society News.—Drs. Frank Wilson Jr., Raleigh, and Robert B. Rodman, Wilmington, addressed the Robeson Medical Society, Wrightsville Beach, October 19, on "Perforated Peptic Ulcer" and "The Neuroses" respectively. Dr. Coy C. Carpenter, Wake Forest, addressed the Greensboro Medical Society, Lumberton, in October on diagnosis and treatment of anemia.—Dr. James W. Tankersley, Greensboro, recently on "Splenomegaly, Its Physiology, Pathology and Treatment."—Drs. Hillis L. Seay, Huntersville, and Thomas C. Bost, Charlotte, October 17 on treatment of tuberculosis and the technique of treating hernia, respectively.—A symposium on sulfanilamide and sulfapyridine was presented before the Buncombe County Medical Society, Asheville, November 6 by Drs. John C. Young, Wilson Pendleton and John LaBruce Ward. A symposium on the common cold from the point of view of the nose and throat physician was presented by Drs. Lewis M. Griffith, Cecil L. Crump and Cecil C. Swann. All are of Asheville.

NORTH DAKOTA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1 with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$5 if a resident of North Dakota or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and \$0.50 each month of default.

OHIO

Personal.—Dr. Carlos Eugene Pitkin, assistant clinical professor of otolaryngology at Western Reserve University School of Medicine, Cleveland, has been promoted to clinical professor, succeeding the late Dr. William B. Chamberlin. Dr. Pitkin has been a member of the faculty for twenty-three years.

Toledo Clinic Day.—Dr. Francis D. Murphy, Milwaukee, was the guest speaker at the annual clinic day sponsored by the Academy of Medicine of Toledo and Lucas County November 17. Dr. Murphy spoke in the afternoon on "Some Phases of Jaundice and Its Significance" and "Hypertension and Nephritis." The morning was devoted to clinics at Mercy Hospital.

Society News.—Dr. William H. Weir, Cleveland, discussed "Conservatism in Certain Gynecologic Conditions" at the meeting of the Academy of Medicine of Cincinnati November 28 under the auspices of the Cincinnati Obstetrical Society.—Dr. Herman W. J. Koerber, Columbus, November 15 on "Toxemia of Pregnancy."—Dr. Frederic Schreiber, Detroit, addressed the Summit County Medical Society, Akron, December 9 on "Cerebral Anoxia and Anesthesia."—Dr. Tom Douglas Spies, Cincinnati, addressed the Academy of Medicine of Cleveland December 15 on "The Vitamin B Deficiencies."

PENNSYLVANIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually on or before January 1 with the board of medical education and licensure in the department of public instruction and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Society News.—Dr. Roland S. Aronson, Philadelphia, addressed the Northampton County Medical Society, Easton, November 17 on the cancer control program in Pennsylvania.—Drs. John Eiman, Abington, and Damon B. Pfeiffer, Philadelphia, November 9 on "Broader Aspects of Arterial Diseases with Special Reference to Etiology" and "Carcinoma of Rectum and Rectosigmoid" respectively.—A symposium on pneumonia was presented before the Westmoreland County Medical Society at the Mountain View Hotel near Greensburg November 21 by Drs. Bernard J. McCloskey, Johnstown; Carl E. Ervin, Harrisburg, and James W. Strang, Pittsburgh.

Philadelphia

National Defense on the Program.—The Philadelphia County Medical Society held its second annual "National Defense Night" November 27. The speakers were: Lieut. Col. John F. Corby, Philadelphia, The New Army Medical Service; Lieut. Col. William D. Fleming, Edgewood Arsenal, Md., Medical Aspects of Chemical Warfare; Dr. Robert Olesen, U. S. Public Health Service, New York, Quarantine Too Is Streamlined; Lieut. Comdr. Herbert L. Pugh, Naval Hospital, Philadelphia, Activities of the Naval Medical Corps in Guam. A film prepared by the War Department, "Chemical Warfare Company in Combat," was shown.

Pittsburgh

Society News.—Dr. William James Gardner, Cleveland, will address the Allegheny County Medical Society, December 19 on "Development of Modern Surgery of Brain." Other speakers will be Drs. John Day Garvin on "When Does a Duodenal Ulcer Become Surgical?"; Thomas C. Wilkinson, "Treatment of Tetany with Dihydroxyacetone" and Gregg A. Dillinger, "A True Evaluation of Tonsillectomy by Electrocoagulation."

SOUTH CAROLINA

Personal.—Dr. James C. Brabham, formerly of Johnsonville, has been made health officer of Colleton County with headquarters at Walterboro, succeeding Dr. Clarence L. Gnyton, who has been placed in charge of cancer control work of the state department of health.—Dr. Charles M. Moore, St. George, former health officer of Dorchester County, has been appointed director of the new inobile syphilis clinic in Charleston County.

Society News.—Dr. Nathan B. Van Etten, New York, President-Elect of the American Medical Association, addressed the Columbia Medical Society recently on "The Quality of Medicine." Dr. James E. Boone, Columbia, presented a paper on "Prophylaxis of Recurrent Renal Calculi." Dr. Allen F. Voshell, Baltimore, addressed the society recently on "Of Forgotten Facts About Fractures," and Dr. James R. Allison, Columbia, on "Twenty Years' Experience in the Treatment of Skin Cancer."—Dr. Emory Hill, Richmond, Va., was the guest speaker at the annual meeting of the South Carolina Society of Ophthalmology and Otolaryngology in Columbia November 7. His subject was "Some Problems of Cataract Surgery."

SOUTH DAKOTA

Health Officers Elect.—Dr. Henry Russell Brown, Watertown, was elected president of the South Dakota Health Officers Association at its annual meeting in October. Dr. Robert S. Westaby, Madison, was made vice president and Dr. John F. D. Cook, Pierre, reelected secretary.

TENNESSEE

Society News.—Dr. William H. Sebrell Jr., Washington, D. C., of the U. S. Public Health Service addressed the Sullivan-Johnson Counties Medical Society, Bristol, November 1 on diseases of nutritional deficiency with special emphasis on pellagra.—Drs. Ernest Marcus and Charles K. Slade, Mountain Home, among others, addressed the Washington County Medical Society, Johnson City, November 2 on "Some Untoward Reactions in Arsenamine Therapy" and "Serial Pyelography" respectively.—Dr. Barney Brooks, Nashville, addressed the Nashville Academy of Medicine and Davidson County Medical Society, Nashville, December 5 on surgery of the thyroid gland.—Speakers before the Dyer, Lake and Crockett Counties Medical Society November 1 were Drs. Frank D. Linn, Memphis, on "Mastoid Disease"; Clyde V. Crowell, Memphis, on "Administration of Fluids"; and Robert L. Sanders, Memphis, "Peptic Ulcer: Diagnosis and Management."—Drs. Gilbert M. Roberts and Edward F. Buchner Jr. addressed the Chattanooga and Hamilton County Medical Society November 23 on "Chronic Nonpurulent Urethritis in Women" and "Ten Year Study of Local Maternal Mortality" respectively.

TEXAS

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1 with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1 his license is suspended.

Tri-State Meeting.—The thirty-fourth annual meeting of the Tri-State Medical Society of Louisiana, Arkansas and Texas was held in Marshall November 8-9 under the presidency of Dr. Joseph D. Roberts Jr., Longview. Among the speakers were:

Dr. Guy A. Caldwell, New Orleans, Foot and Leg Deformities in Infants and Young Children Associated with Overweight.
Dr. Millard F. Arbutnot, St. Louis, Bronchoscopy as an Aid in the Diagnosis and Treatment of Diseases of the Pulmonary Tract.
Dr. Calvin R. Hannah, Dallas, Toxemia of Pregnancy.
Dr. George B. Fletcher, Hot Springs National Park, Ark., Underwater or Pool Treatment of Certain Abnormal Conditions of Muscles, Nerves and Joints.
Dr. Charles T. Stone, Galveston, Vitamin K and Its Clinical Application.

WEST VIRGINIA

Public Health Meeting.—Dr. William H. Riheltdaifer, Romney, was elected president of the West Virginia Public Health Association at its annual meeting in Fairmont November 6-8. Among speakers at the meeting were Drs. Karl A. Menninger, Topeka, Kan., on "Should a Democracy Be Concerned with the Mental Health of Its Citizens?"; Joseph W. Mountin, U. S. Public Health Service, "What Should a Public Health Program Include?"; and Halbert L. Dunn, chief of vital statistics division, U. S. Bureau of the Census, Washington, "Democracy in the Everyday Administration of Public Health."

GENERAL

Prize for Research in Ophthalmology.—The trustees of the Association for Research in Ophthalmology announce that a cash prize of \$100 will be awarded at the 1940 meeting for the paper which in their judgment shows most originality and exemplifies best the spirit of research in ophthalmology.—Dr. Cecil S. O'Brien, University Hospitals, Iowa City, is secretary of the association.

Hygiene Association Disapproves Sex Lecturer.—The American Social Hygiene Association requests publication of a statement that the use of the association's name in certain sex publications by one Mrs. Jardine McCree is unauthorized and heartily disapproved. The association has received reports from various parts of the country that Mrs. McCree is giving lectures and showing films on sex that are objectionable. In a booklet sold in connection with the lectures entitled "Sex Problems and Advice" the name and address of the American Social Hygiene Association is printed, giving the impression that the woman is in some way connected with the organization.

Warning Against Impostor.—An Iowa physician sends a warning against one William J. Collins, who represents himself as a physician and a war veteran. Collins recently telegraphed to an Iowa town for a physician to meet the train on which he was arriving. He then decided to stop there. He appeared to be suffering from carcinoma of the bladder with profuse hemorrhage, and was also a morphine addict. He had medical and nursing care at a hotel and asked to have bills sent to the Veterans Administration. The facility at Hines, Ill., to which the bill was sent, reported that Collins had several times incurred expenses without authority and requested to have the bills sent to that hospital. No record of his case exists there, it was stated. In addition to his expenses he borrowed \$36.20 from the physician who attended him, giving a bad check therefor. Collins said he lived at Lake Worth, Texas. The American Medical Association, however, has no record of a physician of that name licensed to practice in Lake Worth.

Special Society Elections.—Dr. Charles A. Doan, Columbus, was elected president of the Central Society for Clinical Research at its twelfth annual session in Chicago November 3-4, succeeding Dr. Walter H. Nadler, Chicago. Dr. Lawrence D. Thompson, St. Louis, secretary-treasurer of the society, was made vice president and Dr. Carl V. Moore, St. Louis, secretary-treasurer. The 1940 session will be held in Chicago November 1-2.—Dr. Harry R. Foerster, Milwaukee, was elected president of the American Academy of Dermatology and Syphilology at its annual meeting in Philadelphia November 6-8. Dr. Clark W. Finnerud, Chicago, was made vice president and Dr. Earl D. Osborne, Buffalo, reelected secretary. Next year's meeting will be in Chicago.—Dr. Thomas T. Mackie, New York, was named president-elect of the American Society of Tropical Medicine at the annual meeting in Memphis, Tenn., November 21-24; Malcolm H. Soule, LL.D., Ann Arbor, Mich., vice president, and Dr. E. Harold Himman, Wilson Dam, Ala., secretary. Dr. Louis L. Williams Jr., Washington, D. C., became president.

Changes in Status of Licensure.—The Illinois Department of Registration and Education announces the following:

The Michigan State Department of Registration in Medicine announces the following:

Dr. Charles L. Soper, Barryton, Mich., license revoked recently for unprofessional conduct.

The Pennsylvania State Board of Medical Education and Licensure has reported the following action:

Dr. Henry L. Westermann, Pittsburgh, license revoked recently because of his breaking parole after conviction in federal courts.

The Texas State Board of Medical Examiners recently reported:

John G. Townsen, Lampasas, Texas, license reinstated July 30; it was revoked in 1934.

The State of Utah Department of Registration recently reported the following action:

Dr. Afton M. Livingston, whose last known address was Manti, Utah, license restored August 1.

Society News.—The American Social Hygiene Association announces the fourth annual Social Hygiene Day to be observed Feb. 1, 1940. Plans indicate that there will be more than 5,000 community and regional meetings will be over the country. Among features of the observance will be the release of a new sound motion picture entitled "With These Weapons." Those desiring information concerning participation in the observance are asked to write to Social Hygiene Day Service, American Social Hygiene Association, 50 West Fifth Street, New York.—The United States Chapter of the International

College of Surgeons will hold its fourth annual assembly at Venice, Fla., Feb. 11-14, 1940. There is no registration fee. For general information address Dr. Fred H. Albee, 57 West Fifty-Seventh Street, New York; for information about presentation of papers or exhibits write to Dr. Charles H. Arnold, secretary of the scientific assembly, Terminal Building, Lincoln, Neb.—Dr. Amos L. Beagler, Denver, was elected president of the American School Health Association at the annual meeting in Pittsburgh in October.—The American Student Health Association will hold its annual meeting at the Hotel New Yorker, New York, December 28-29.—New officers of the Central Neuropsychiatric Association are Drs. Percival Bailey, president, Chicago; Francis A. Ely, Des Moines, vice president, and William C. Menninger, Topeka, Kan., secretary-treasurer. The 1940 session will be held in October in Milwaukee.—The Phi Lambda Kappa Medical Fraternity will hold its thirty-second annual convention in New York December 30-January 1 at the Park Central Hotel.

Eighth American Scientific Congress.—The Department of State announces that the Eighth American Scientific Congress will be held in Washington, D. C., May 10-18, 1940, under the auspices of the government of the United States. The meeting will be one phase of a celebration of the fiftieth anniversary of the founding of the Pan American Union. The congress will be divided into the following sections: anthropologic sciences, biologic sciences, geologic sciences, agriculture and conservation, public health and medicine, statistics, history and geography, international law, public law and jurisprudence, economics and sociology, education. The official languages will be English, Spanish, Portuguese and French. Papers may be presented in any of these languages and arrangements will be made for presentation of the papers or résumés thereof in the other languages. Secretary of State Cordell Hull has appointed the following organizing committee to cooperate with the Department of State in formulating plans:

The Honorable Sumner Welles, under secretary of state, chairman.
Warren Kehlner, acting chief, division of international conferences, Department of State, vice chairman.

Alexander Wetmore, Sc.D., assistant secretary, Smithsonian Institution, secretary and secretary general of the congress.

Charles G. Abbot, LL.D., secretary of the Smithsonian Institution.
Isaiah Bowman, LL.D., president, Johns Hopkins University, Baltimore.

Vannevar Bush, D.E., president, Carnegie Institution of Washington.
Ben M. Cherrington, Ph.D., chief, division of cultural relations, Department of State.

Mr. Laurence Duggan, chief, division of the American republics, Department of State.

Dr. Ross G. Harrison, New Haven, Conn., chairman, National Research Council.

Waldo G. Leland, secretary, American Council of Learned Societies.
Mr. Archibald MacLeish, librarian of Congress.

Dr. Thomas Parran, surgeon general, U. S. Public Health Service.
Stuart A. Rice, Ph.D., chairman of the Central Statistical Board.

Leo S. Rowe, LL.D., director general, Pan American Union.
James Brown Scott, J.U.D., trustee and secretary, Carnegie Endowment for International Peace.

This congress is an outgrowth of the First Latin American Scientific Congress held in Buenos Aires in 1898. The second was in Montevideo in 1901 and the third in Rio de Janeiro in 1905. In 1908 the United States was invited to participate and the name was changed to the First Pan American Scientific Congress. Subsequent meetings were held under this name in Washington in 1915, Lima, Peru, in 1924 and Mexico City in 1935. The latter session, in recognition of the continuity of the preceding congresses, was called the Seventh American Scientific Congress.

FOREIGN

Kitasato Institute Twenty-Five Years Old.—The Kitasato Institute for Infectious Diseases celebrated its twenty-fifth anniversary November 5. The institute was founded by Baron Kitasato, the Japanese bacteriologist who discovered the bubonic plague bacillus, after he had served many years as director of the Imperial Japanese Institute for the Study of Infectious Diseases. Baron Kitasato was born in 1856 and died in 1931.

Ear, Nose and Throat Congress Postponed.—The committee of the Fourth International Oto-Rhino-Laryngological Congress, which was to have been held in 1940 in Amsterdam, has been postponed indefinitely. Dr. A. Marres, Willemsparkweg 31, Amsterdam, is secretary of the congress. The committee expresses the hope that "the present horror will give way to better times and that at some future date it may be granted to us to send our invitation once more to the otorhinolaryngological world."

New Medical Center in Sweden.—The Carolinian Hospital, part of a new medical center in Stockholm, Sweden, is nearing completion, according to a recent announcement. The hospital will provide accommodations for about 1,500 patients

and more than 1,000 doctors, nurses and other personnel. On the roof of the main buildings there will be a sun terrace 650 feet long. A mural painting on the ceiling of the vestibule by Prince Eugen of the royal family represents the aims of medical science. Provision is being made to protect the hospital from air raids. Subterranean rooms are being blasted in the rock under the hospital to make shelters and an emergency hospital. The medical center, which includes numerous buildings for research, isolation, administration, training, housing and a college of nursing, will provide training and study facilities for the students of the Carolinian Medico-Surgical Institute, which is gradually moving into the new premises. Among buildings already opened are a home for the crippled and the "Radium Home," a cancer hospital. The eventual cost of the center will be about \$10,000,000, of which about two thirds has been expended.

Deaths in Other Countries

Edward Palmer Poulton, senior physician to Guy's Hospital, London, England, died October 18 at Tunbridge Wells, aged 56. Dr. Poulton was well known for his work on several editions of Taylor's Practice of Medicine.—**Prof. Dr. Freiherr v. Eiselsberg**, head of the First Surgical University Clinic at Vienna, aged 79, died October 26 of skull fracture resulting from a railroad accident en route from his estate near Wels to Vienna. Professor Eiselsberg and Dr. Julius Wagner-Jauregg were the only two remaining in good health who had seen the brightest period of the Medical Faculty of Vienna.—**Dr. Wilfred Trotter**, sergeant surgeon to the king of England since 1932 and professor of surgery at the University College Hospital Medical School, died November 25 at Blackmoor, Hampshire, England, aged 67.

Government Services

Dr. Griffiths Goes to Puerto Rico

Dr. Thomas H. D. Griffiths, senior surgeon of the U. S. Public Health Service and director of the Henry R. Carter Memorial Laboratory, Savannah, Ga., has been transferred to Puerto Rico and the Virgin Islands, it is reported. He will be succeeded at the laboratory by Dr. Charles M. McGill, assistant surgeon, U. S. Public Health Service. Dr. Griffiths has been in Savannah since 1937, when the memorial laboratory was opened.

New Members of Advisory Cancer Council

Drs. Max Cutler, director of the Chicago Tumor Institute, and George M. Smith, research associate in anatomy, Yale University School of Medicine, New Haven, Conn., have been appointed members of the National Advisory Cancer Council to succeed Dr. Ludvig Hektoen, Washington, D. C., and Clarence C. Little, Sc.D., Bar Harbor, Maine, whose terms have expired. The Council held its first quarterly meeting in the new National Cancer Institute near Bethesda, Md., December 4. Continuing members are James B. Conant, Ph.D., president of Harvard University, Cambridge, Mass.; Arthur H. Compton, Ph.D., Chicago; Drs. Mont R. Reid, Cincinnati, and James B. Murphy, New York.

Positions Open at St. Elizabeths

The United States Civil Service Commission announces open competitive examinations for two positions as junior medical officer at St. Elizabeths Hospital, Washington, D. C., one a rotating internship and the other a psychiatric residency. Both carry salaries of \$2,000 a year. The internship consists of a rotating service of four months of surgery, four months of acute medical service, four months of chronic medical service, two months of obstetrics, two months of pediatrics, three months of general laboratory work and six months of psychiatry. The residency is a postgraduate internship of one year, offered to graduates in medicine who have already served an accredited internship. Application forms may be obtained from the secretary of the board of civil service examiners at any first class post office, from the commission at Washington or from the district office in any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, C. Z., and San Juan, P. R.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Nov. 11, 1939.

The Chemotherapy of Infected War Wounds

The war office has distributed to all officers of the Royal Army Medical Corps a memorandum on the treatment of infected war wounds by the sulfonamide derivatives which may be taken as reflecting the authoritative British view on these substances. As they have been shown to be effective in streptococcal infections and also to have an action on anaerobic gas forming bacilli, it is recommended that they be given a trial in the field. The earlier the treatment the better the result, but some benefit may be anticipated even in established infections. All wounds which appear likely to become the site of secondary cocci or gas gangrene infection should receive as soon as possible a prophylactic course of sulfonamide treatment, which should occupy about forty-eight hours. For developing or established infections the course should extend over ten days, but if not then effective an interval of forty-eight hours should be allowed before continuing treatment. When an infection appears to be controlled, as judged by the temperature, small doses should be continued for a further three to five days in order to prevent relapses. The principle of effective treatment is to obtain a high blood concentration of the drug as soon as possible and to maintain this at an effective level for a time. As the drugs are rapidly excreted, to maintain an effective level it is necessary to administer them at four hour intervals day and night.

The dose of sulfanilamide recommended for prophylaxis is 4 Gm. at once followed by 2 Gm. after four hours and then by 1 Gm. every four hours day and night. If, after ten days, infection is still uncontrolled, allow an interval of forty-eight hours and then repeat the same course from the beginning or, if available, change to sulfapyridine. If infection appears to be controlled during the first or later courses, reduce the dose to 0.5 Gm. and continue for three to five days after the temperature has become normal. If during the first course of treatment no effect is evident in three days, a change to sulfapyridine is recommended.

For sulfapyridine treatment powdered tablets should be administered in milk or water. If vomiting is troublesome the dose should be split and administered at shorter intervals. For prophylaxis 3 Gm. should be given at once followed by 2 Gm. in four hours and then by 1 Gm. every four hours day and night for forty-eight hours. Soluble sulfapyridine is of great value when swallowing is impossible or gastric trouble prevents absorption. It may be injected intramuscularly or intravenously in doses of 1 Gm. every four hours day and night. The prophylactic course is completed in forty-eight hours. For treatment the course may be continued for ten days, but a change should be made to the oral compound as soon as possible. The soluble compound finds its best use in the initial phases of a course of treatment and should not be regarded as a substitute for the oral compound. It should be used for a continuous course only when oral therapy is impracticable.

Traffic Accidents Increased by the Blackout

The danger of air raids prevents street lighting and compels the screening of traffic lights and the confining of illumination to interiors. The result at night is a condition of darkness for which the term blackout is used. The result is a great increase in traffic accidents. In October 919 persons were killed in these accidents, against 641 in October 1938 and 1,130 last September, the first month of the blackout. The returns show for the first time the number of fatalities during the hours of darkness. Of 572 pedestrians killed in October, 424 were killed in the darkness; the total number of persons

killed was 564. In London the fatalities in October numbered 131, of which eighty-four occurred in the darkness. If the number of deaths in road accidents in the blackout continues at the present rate, in a three years war it will total nearly 40,000. At a press conference arranged by the "National Safety First Association," it was stated that an analysis shows that about one third of those killed in traffic accidents since the war started were over 70 years of age, one third between 60 and 70, one sixth between 50 and 60, and one sixth under 50. If elderly people refrained from going out during the blackout except when absolutely necessary, accidents would be greatly reduced. It has been found that a large percentage of the accidents are caused by pedestrians stepping into the path of a car in the belief that the driver would see them. The pedestrian has not been able to get rid of his peace time road psychology and thinks he will be seen.

Special Types of Injuries in Air Raids

The extent of the arrangements for the treatment of injuries to civilians in air raids is shown by the provision by the government of special centers where certain types of disability can be collected and treated by specialist staffs. But it is recognized that in the early stages of an emergency it is likely to prove impracticable to divert systematically these cases to such special centers, owing to difficulties in switching suddenly over from a central peace time to a decentralized war time organization, and to the impossibility of foreseeing the conditions in which it will be necessary to work in the first instance. Nevertheless the locality of the special centers is being pre-arranged and they will function at the earliest possible moment. In the case of neuroses uncomplicated by any injury, an endeavor will be made from the outset to dispose of those requiring special treatment, that is, unfit to be sent home, by sending them to the special institutions to be established. Plans are being made for collecting from the central hospitals such special equipment as is necessary. Specialist staffs also are being selected.

The Illicit Drug Traffic

In spite of the efforts of the League of Nations to check the illicit drug traffic, it still continues on a large scale. In the House of Commons a member pointed out that, while good work toward its suppression has been shown by most governments, the Japanese fostered the consumption of drugs not only in China but all over the world, including Canada, and they smuggled cocaine into India.

Mr. Butler, undersecretary for foreign affairs, said that the government viewed with grave concern the drug situation described by the Opium Advisory Committee last June and reviewed by the League of Nations this autumn. A serious feature was the growth of the use of heroin, the effects of which were far more serious than those of opium. In 1936 there was an Anglo-Japanese drug traffic agreement. No immediate action followed till they arranged this autumn for closer cooperation with the Japanese government. The information in his possession did not show that the increase of the drug traffic in China was the outcome of any deliberate plan of the Japanese government. In North China, the central government attempted to enforce drastic opium and narcotic laws, but since the Japanese occupation these deterrents had disappeared. In central China the position did not seem so serious. The British government intended to continue its efforts in cooperation with other governments.

Closure of the Ductus Arteriosus—A Correction

In the London letter in *THE JOURNAL* June 24, page 2617, reference was made to the paper by Barclay, Barcroft, Barron and Franklin in the *British Journal of Radiology* reporting identification of the ductus arteriosus in the newborn lamb. The same authors in the September issue of the *British Journal*

of Radiology report that, since that time, owing to improvements in technic, they have found that their report was erroneous. The shadow which was then described as that of the ductus is really that of a branch of one of the pulmonary arteries.

BERLIN

(From Our Regular Correspondent)

Nov. 8, 1939.

Race and Heredity

Since the report on heredity and race in *THE JOURNAL* July 29, page 434, additional information has become available. It has been decided to avoid using the term "Aryan" in official publications. Dr. Gross, director of the state bureau of race and politics, explained this to an assembly of leaders of the Hitler Youth movement. It is difficult, he said, to define the term "Aryan" because the expression is derived from philology and does not always coincide with present racial knowledge. For that reason the terms cross breeds (*mischlinge*) of the first and second grade have been adopted. This corresponds to terminology used in cattle raising. (See *THE JOURNAL*, Sept. 8, 1934, p. 764, for criticisms of the use of "Aryan" in the sense given it in Germany.)

A race museum is to be founded in Berlin to serve primarily the idea of race significance as a universal political concept. Attention is called to the remarks made by an official representative at the second university week at Karlsruhe: "Efforts to measure race craniologically are likely to introduce explosive matter into the unity of the German people." Heretofore cranial measurements as factors in race determination have been popular. A Jewish physician in Hamburg, 52 years old, was sentenced in July of this year to fifteen years in the penitentiary and ten years of civic degradation because of being involved in five cases of race pollution; that is, intercourse with Aryan women. To promote the study of heredity, local health bureaus have been ordered to keep official records of multiple births; that is, of twins, triplets and so on, as well as records of consanguineous marriages. Statistics of this kind are regarded as valuable for the biology of heredity.

Hereditary diseases are also exploited with official approval on the stage. A strolling theatrical company is presenting a play which in itself is of no significance and perhaps would never have been written or shown without government support. The play hinges on the idea that epilepsy was discovered in the bridegroom. The betrothal is annulled and the man sterilized. This play was presented also during a "district cultural week."

The danger of asocial persons to the welfare of the nation has been made the object of extensive investigations by the same bureau on race and politics in Bremen and Saxony. It is alleged that the evaluation of the facts already secured makes possible proof that asocial persons constitute a biologic danger. The first publication of the results of investigation concern three asocial families. Dr. Knorr, of the same bureau, regards asocial persons as an inferior biologic stock and the task of reducing the progeny in such families as the most important problem in the purification of heredity stocks. While the size of the average German family is insufficient to prevent a decline in population, the number of children in asocial families is several times as large. The investigations conducted did not deal with criminals and gypsies but with asocials who stand out not because of individual criminal acts but because of their general incapacity for social cooperation. On the basis of these investigations, Knorr contradicts the customary view that asocials are found in families otherwise useful and that their descendants ought to be preserved. The investigations, he says, show that nearly all members of investigated families and their kin are incapable of social cooperation. These asocial characteristics have been transmitted by heredity. The offspring of such marriages is unusually high. The menace

represented by asocials is not of a medical nature but one of character. A law making it possible to sterilize such descendants who have early manifested asociality would essentially reduce this inferior social stock within a few generations. It was stressed that asocial persons may not be placed in the same category with persons hereditarily diseased in the legal sense of the word.

The Serum Treatment of Poliomyelitis

The waves of poliomyelitis which have swept over Denmark almost every late summer and autumn in recent years should have given opportunities, one would have thought, for testing the efficacy of the serum of convalescents. In the outbreak of 1934, for example, serum was administered in about 80 per cent of all the well defined cases, and Dr. Claus Jensen, who undertook a statistical study of this year's cases, formed a favorable opinion of this treatment. Yet faith in it has languished ever since, many clinicians, as distinct from statisticians, having been disillusioned in this matter. So when in 1937 a new outbreak occurred, the Blegdam Fever Hospital serving Copenhagen dispensed with this treatment. It was only in the provinces in 1937 that a lingering belief in the efficacy of serum secured its employment in a limited number of cases.

In 1939 Dr. E. Juel-Hemmingsen and Dr. G. Rasch issued a study of this problem with reference to the outbreak of poliomyelitis in 1937. They sent a questionnaire to the hospitals, which had dealt with more than a thousand cases that year, and analyzed the answers. In the provinces there were 489 patients receiving serum treatment and 400 who received no serum. While 60 per cent of the latter developed paralysis, only 33 per cent of the recipients of serum did so. Another comparison, much less favorable to serum, was made between 409 serum-treated patients who were not paralytic on admission to the hospital and 200 patients who were not given serum and who were also not paralytic on admission. Subsequently 18.1 per cent of the serum-treated group and 19 per cent of the controls developed paralysis. The scoffing clinician must feel tempted by such results to suspect the statistician of being capable of coming to any result he likes by an adroit reshuffling of the cards. At all events in Denmark at present there is a conviction that the wholesale early treatment of poliomyelitis with the serum of convalescents still lacks convincing proofs of its efficacy.

The Pirquet or the Mantoux Test?

The Norwegians usually employ the Pirquet test, while the Danes prefer the Mantoux test, which they consider much more delicate and accurate. The Norwegians have found that two consecutive Pirquet tests on Mantoux-positive persons give positive reactions in from 90 to 95 per cent. Thus they consider good enough and they continue to prefer the Pirquet test for wholesale examinations of children, holding that its comparative simplicity compensates for the small margin of error inherent in it. The Danes, however, have found that only from 50 to 70 per cent of their Mantoux-positive reactors also give a positive reaction to the Pirquet test; hence the disfavor into which it has fallen in Denmark. Swedish observers are, on the whole, inclined to side with the Danes in this matter, though tuberculin testing in Sweden has not brought such general discredit on the Pirquet test as it has in Denmark.

To clear up this minor dispute, Dr. T. Madsen, of the State Serum Institute in Copenhagen, and Dr. O. Scheel, of the Ullevaal municipal hospital in Oslo, arranged a combined Norwegian-Danish investigation. Dr. J. Holm represented Denmark and Dr. H. J. Ustvedt represented Norway. They worked together in Copenhagen, testing 258 school children

and seventy-two young adults. When the Pirquet test was repeated twice, it gave a positive reaction in 90 per cent of the Mantoux-positive children and in 87 per cent of the Mantoux-positive young adults. These investigators suggest that reinfections maintain sensitiveness to tuberculin and that the more a community is rid of tuberculosis the greater will be the proportion of Pirquet-negative persons among the Mantoux positive. And Norway, with its comparatively high tuberculosis morbidity, must therefore provide a greater proportion of Pirquet-positive reactors than Denmark.

Gonorrhea and Modern Chemotherapy

In a report recently presented to the Danish Medical Society, Dr. Aage Kristjansen produced statistics on the treatment of gonorrhea at the Rudolph Bergh Hospital in Copenhagen. In 1937 treatment of gonorrhea with the sulfanilamide group of drugs was instituted, and by the end of June 1939 between 400 and 500 patients had been treated with a Danish preparation of sulfanilamide or the English preparation sulfapyridine. A comparison of the effects of these two preparations was so unfavorable to the former that sulfapyridine has displaced it altogether. While sulfanilamide is apt to be inert early in the disease, sulfapyridine seems to be equally potent whatever the stage of the disease or the sex and age of the patient. Sulfapyridine possesses the further advantage of inflicting fewer and less serious complications and manifestations of drug intolerance than sulfanilamide. Now that a recent attack of gonorrhea can be more readily cured under ambulatory conditions, the claims on hospital beds for the treatment of gonorrhea have dwindled enormously. In 1930 about 59 per cent of the 180 beds in the Rudolph Bergh Hospital were required for the treatment of venereal disease, whereas at present only 10 per cent are required for this purpose. This decline cannot be credited exclusively to the sulfanilamide group of drugs, for bismuth compounds have also played a part in reducing the number of patients requiring hospital treatment for syphilis.

BUENOS AIRES

Cultural Relations with the United States

The number of Argentine physicians and members of other scientific professions who go to the United States for postgraduate studies has increased during the last few years, especially through Professor Houssay's influence. The number is increasing still more because of present conditions in Europe. The main difficulty is the increased rate of exchange, which makes the cost of living and the expense of the trip very high. Requests have been made of American steamship companies to make special reductions for students, such as are allowed them by English, Italian, German and French steamship companies; namely, a reduction of 25 or 50 per cent. However, no reduction is allowed on American ships. The number of persons who may go to the United States with Argentine scholarships is not more than twelve a year. They have scholarships from the Comisión Nacional de Cultura, Asociación Argentina para el Progreso de las Ciencias and Academia Nacional de Medicina. They are persons who are devoted to research or to teaching and who had secured positions on their return home. Argentines who have been sent to foreign countries with scholarships have obtained important positions in Argentina, such as professors in faculties, heads of laboratories or of some national institution. A reduction in the cost of the trip would aid the financial condition of students.

Medical Congresses

During the present year the Academia Nacional de Medicina of Buenos Aires held a monthly meeting for the discussion of allergy. Official speakers were Prof. A. Sordelli (who discussed

classification of phenomena of allergy and hypersensitivity), Prof. B. A. Houssay (physiologic mechanisms of allergy), Prof. A. Bachmann (allergy and anaphylaxis) and Prof. P. I. Elizalde (pathologic anatomy). Drs. P. Baliña, Segura, Argañaraz, Castex, Raimondi, Bullrich, Araoz Alfaro, E. Finochietto, P. I. Elizalde, Peralta Ramos and Cabanne discussed allergy in relation to dermatology, otorhinolaryngology, ophthalmology, renal diseases, asthma, circulatory diseases, tuberculosis, serum sickness, pediatrics, gynecology and obstetrics, and odontology.

The Asociación Médica Argentina held two meetings, at which the official topics were respectively gastrointestinal hemorrhages and adrenal insufficiency. Drs. J. T. Lewis, E. B. del Castillo, E. Hug and M. Soto were official speakers at the second congress.

The Congreso Argentino de Cirugía held its annual reunion October 8-13 under the chairmanship of Dr. Roberto Sole. The Brazilian delegation was represented by Drs. A. Monticoro and J. Gudín. Drs. García Valenzuela and Vargas Molinare, of Chile, and Ramon Doria, of Paraguay, also were present. The first official topic was "calculi of the biliary tract." Official speakers for the first topic were Prof. E. Blanco Acevedo, of Montevideo, and P. Mirizzi, of Córdoba. Drs. A. J. Bengolca, Velasco Suarez, D. del Valle and I. M. Allende read papers. Bengolca, who reviewed 972 operative cases, emphasized that special consideration should be given to the preoperative period. He advises against routine cholecystectomy and uses frequently the Kehr tube. Prof. P. Mirizzi performs, as a routine procedure, cholangiography during operation with the aim of determining the position of calculi. He advised supraduodenal choledochotomy for removing the calculi from the common bile duct. In many cases he sutures the common bile duct without any drainage. The satisfactory results of operations in biliary calculus obtained by Professor Mirizzi are well known. He does not believe in unnecessary delay before performing an operation in cases of calculous occlusion of the common bile duct. Professor Mirizzi recently published a book on the functions of the biliary tract. He states that cholangiography shows that in the functions of the biliary tract three different sphincters are concerned: Oddi's, the sphincter of the gallbladder and that of the hepatic duct, which exists immediately above the joint between the cystic and the hepatic ducts.

Profs. Eduardo Villa and Jose Puente discussed the second official topic, varices. Prof. E. Cornejo Saravia (a pupil of Prof. Pedro Chutro) was the speaker for the third official topic, treatment of malleolar and supramalleolar fractures. Surgical demonstrations were performed in all hospitals of Buenos Aires for three days.

Tendencies in Sanitation

Several subjects relating to the organization of medicine and sanitation were discussed at the Congress of Sanitation, recently held in Santa Fe. The following motions were approved: autonomy of the main department of hygiene, permanent positions for the technicians in sanitation, full time for the personnel working in sanitation, recognition of professional dangers, jubilation and retirement, extension of pre-nuptial certificates of health to women, and maintenance of medicine. It was resolved to organize the Congreso de la Asistencia Social, which will be held next year in Rosario.

Personals

Prof. J. J. Spangenberg was recently appointed, by the government, president to the Departamento Nacional de Higiene and to the Comisión de asilos y hospitales regionales.

Dr. Juan Bacigalupo was appointed professor of parasitology at the Faculty of Medicine of Buenos Aires. He will occupy the chair vacated by Dr. D. Greenway, who reached the age limit.

Prof. Jose Arce gave a lecture of farewell from his chair of surgical clinic, which he intended to resign, after which he decided to remain.

Dr. Atilio Costa was appointed professor of surgical technic at the Faculty of Medicine of Buenos Aires.

The following persons were presented with scholarships: Dr. Flaminio Vidal, a scholarship from the Rockefeller Foundation, to work with Dr. S. W. Ranson, of Chicago, on neurology, anatomy and physiology. Miss Inés López Colombo de Allende, a scholarship from the Asociación Argentina para el progreso de las ciencias, to work with Dr. G. W. Corner, of Rochester, N. Y., on sexual endocrinology of primates. Dr. E. de Robertis, a scholarship from the Academia Nacional de Medicina, to work with Dr. William Bloom, of Chicago, on histology. J. Llacer, a scholarship from the Asociación Argentina para el progreso de los ciencias, to work with Professor Benedetti-Pichler, of New York, on microchemistry.

Drs. B. A. Houssay, P. Belou and J. Arce recently celebrated their thirtieth and twenty-fifth anniversaries, respectively, as professors.

Deaths

Dr. G. Bosch Arana, professor of surgical technic at the Faculty of Medicine of Buenos Aires, recently died at the age of 53.

ITALY

(From Our Regular Correspondent)

Oct. 21, 1939.

Treatment of Inguinal Hernia

Professor Lanzillo, in a lecture recently delivered to the Società napoletana di Chirurgia, reported a technic for radical treatment of inguinal hernia which is based on the principle of making a solid posterior wall to the hernia. An incision is made on the large oblique muscle. The lower flap is passed behind the muscular layer of the small oblique and transverse muscles by means of a series of U stitches and is placed in front of the fascia transversalis. The upper flap together with the small oblique and transverse muscles are placed in front of the lower muscular flap and sutured to the bridge. A wall is thus formed in front of the fascia transversalis. It is made up of four layers, namely the lower flap of the aponeurosis of the large oblique, the transverse and small oblique muscles, and the upper flap of the aponeurosis of the large oblique. The cord, in accordance with the circumstances, may be lodged behind the fascia transversalis, between the fascia and the aponeurosis of the large oblique (which makes the back aspect of the wall newly formed), between the aponeuritic flaps or in the subcutaneous connective tissue. The speaker pointed out the advisability of cutting the epigastric vessels and Hesselbach's ligament, which is near the vessels, in the course of any operation for inguinal hernia.

Society Reunion

The Accademia delle Scienze Mediche e Chirurgiche met recently at Naples under the chairmanship of Professor Jappelli. Professors Bakunin and Deza-Cauget doubt the possibility of the formation of so-called total or partial blockage of the reticulo-endothelial system in living animals. From a review of the literature and from their experiments they believe that the phenomenon shows impregnation of the reticulo-endothelial system, which may cause a dysfunction of the system without causing absolute suppression of the function. The speakers adopted the name of impregnation of the reticulo-endothelial system for the phenomenon. The speakers studied rabbits which were impregnated with thorium dioxide sol administered intravenously, intraperitoneally or subcutaneously. Some such animals were inoculated with staphylococcus, streptococcus, pneumococcus or tubercle bacilli of the bovine type, whereas others were kept as controls. The results showed that, notwithstanding the fact that the organic resistance of impregnated animals is diminished in comparison to that of the controls, the lesions caused by staphylococcal infection on the tissues are more acute in the latter than in the former. In subcutaneous inoculation the

abscess formation takes place earlier in control than in impregnated animals and the toxic phenomena are slower in the former than in the latter. The lesions caused by intravenous inoculation are of the septicopyemic type in control and of a nephrosic and necrotic type in impregnated animals. In the groups of animals inoculated with tubercle bacilli of the bovine type the controls reacted with the common reactions, namely development of typical regional adenopathies. Impregnated animals developed massive infection with extensive lesions at the spleen, lungs, liver and adrenal cortex. Inoculation of tubercle bacilli by the intravenous route caused tuberculous lesions of the same acuteness and in the same time in both controls and impregnated animals. The most acute lesions were those of the lung. Tuberculous inoculations caused acute splenomegaly of the macroscopic and microscopic types of splenic lymphogranulomatosis in impregnated but not in control animals. Large reticulo-endothelial multinucleated cells which are commonly found in splenomegaly do not store thorium dioxide sol. However, the epithelioid cells and Langerhans giant cells of tuberculous granuloma had the substance stored.

Professor Bakunin spoke on surgical treatment of wounds and also on the influence of vitamins A and D on the evolution of wounds. The speaker reported a method which consists in early careful cleansing, preparation of the wound and removal of necrotic tissues no later than six hours after trauma, suture of any break in the continuity of the tissues (which may be covered with skin) and reduction of fractures or luxations, if any. The limb must be placed at rest, in an inclined plane, to improve the condition of circulation. It must be placed on sterilized cloth and put in a special wire device which is covered with gauze. The cloth and sterilized gauze are changed at intervals and all fluids eliminated are removed. Cod liver oil is applied to the wound every two or three days by means of a siphon bottle. The wound is free from direct contact with any medication as though it were enclosed in a chamber. The method is applied to wounds and burns. It is economical, easy and efficacious. Wounds or burns quickly heal with rapid formation of clean healthy tissues, a small elastic scar and never a keloid. The author pointed out that both wounds and burns are more or less extensive local lesions which cause pathologic repercussion in the whole system, especially in certain organs or tissues. The most grave organic conditions are those caused by local shock, intoxication from reabsorption of substances which originate in scattered tissues and consequent regeneration of the cells. The anabolic and catabolic changes from trauma have an influence on the whole system. From this point of view one can see that cod liver oil, locally applied, acts directly on the focus and indirectly on the general condition. The efficacy of the treatment is due to vitamins A and D in cod liver oil and probably also to some other substance contained in it.

Marriages

JULIAN LOMBARD, New Orleans, to Miss Bess C. Sheppard of Dallas, Texas, in New York, October 14.

JOHN FAULKNER RAINY, Greenville, S. C., to Miss Caroline Freeman Stringer of Anderson, October 28.

SIDNEY M. REICH, Wilkes-Barre, Pa., to DR. SYLVIA J. RUBENSTONE of Philadelphia, October 7.

JULIUS LIPSON, Otisville, N. Y., to Miss Netty D. M. Blok of The Hague, Netherlands, October 6.

HOWARD S. REID, Cohasset, Mass., to DR. NANA L. ROSENTHAL of Des Moines in October.

GEORGE TOLSTOI, Washington, D. C., to Lenore Oslander of Uniontown, Pa., September 10.

J. ELLIOTT ROYER, Oakland, Calif., to Miss Helen Hay in Reno, Nev., in September.

Deaths

DEATHS

2255

- James E. Sadler** * Poughkeepsie, N. Y.; Albany Medical College, 1887; member of the House of Delegates of the American Medical Association, 1909-1910, 1929-1932; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; fellow of the American College of Surgeons; past president of the Medical Society of the State of New York; medical director of a hospital bearing his name; attending surgeon to St. Francis Hospital; consulting surgeon of the Butterfield Memorial Hospital, Cold Spring, Northern Dutchess Health Service Center, Rhinebeck, and the Sharon Hospital; aged 74; died, October 9, of arteriosclerotic heart disease and coronary occlusion.
- Willard Burr Soper** * New Haven, Conn.; Columbia University College of Physicians and Surgeons, New York, 1908; associate professor of medicine at Yale University School of Medicine; member of the Association of American Physicians and the American Clinical and Climatological Association; fellow of the American College of Physicians; served during the World War; medical director of the William Wirt Winchester Hospital, West Haven, a tuberculosis unit of the New Haven Hospital; aged 56; died, October 30, in the New Haven Hospital of brain tumor.
- Patrick Chalmers Jameson** * Brooklyn; Long Island College Hospital, Brooklyn, 1892; member of the American Academy of Ophthalmology and Otolaryngology and of the American Ophthalmological Society; fellow of the American College of Surgeons; surgeon to the Brooklyn Eye and Ear Hospital, St. John's Hospital, Caledonian Hospital, Brooklyn Hospital and House of St. Giles the Cripple; aged 72; died, October 27, in the Long Island College Hospital of duodenal ulcer, pyloric stenosis and gastro-enterostomy.
- James Lyons Cobham** * Jersey City, N. J.; University of Pennsylvania School of Medicine, Philadelphia, 1917; fellow of the American College of Surgeons; assistant instructor in surgery at the New York Medical College and Flower Hospital from 1932 to 1935; consulting surgeon at the New Jersey State Hospital, Greystone Park; served during the World War; president of the medical staff of the Christ Hospital; aged 44; died, October 9, of coronary occlusion.
- James E. Murphy** * Hartford, Conn.; Medico-Chirurgical College of Philadelphia, 1909; member of the American College of Chest Physicians; for many years resident physician to the Wildwood Sanatorium; on the staffs of the Manchester Hospital, Hartford Municipal Hospital and the Hartford Hospital, where he died, October 31, of staphylococcal sepsis, aged 61.
- Walter Lee Munro** * Providence, R. I.; Harvard Medical School, Boston, 1885; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; consulting surgeon to the Rhode Island Hospital, Joseph's Hospital and the Miriam Hospital, Providence, and the Memorial Hospital, Pawtucket; aged 82; died, October 23, in the Jane Brown Hospital.
- Clarence Whittemore**, Johnson City, N. Y.; Jefferson Medical College of Philadelphia, 1913; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; for many years member of the board of education; on the staff of the Charles S. Wilson Memorial Hospital; aged 48; died, October 23, of heart disease.
- Henry Esson Young**, Victoria, B. C., Canada; McGill University Faculty of Medicine, Montreal, Que., 1888; past president of the Western Branch of the American Public Health Association; provincial officer of health; at one time Provincial Minister of Education and Provincial Secretary; aged 72; died, October 24, in a local hospital.
- George Myrtle Culver** * Jersey City, N. J.; Bellevue Hospital Medical College, New York, 1894; past president of the Hudson County Medical Society; member and at one time member of the board of education; aged 73; died, October 19, of cerebral embolism and arteriosclerosis.
- Stephen Henry Besley** * Salt Lake City; Northwestern University Medical School, Chicago, 1924; aged 49; surgeon to the Utah State Prison and the Salt Lake County General Hospital; on the staff and member of the board of governors of the Holy Cross Hospital, where he died, October 7, of gallstones with multiple liver abscesses.
- William Hasbrouck Snyder** * Newburgh, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1895; member of the American Urological Association; past president of the Orange County Medical Society; at one time health officer; aged 66; died, October 17, in Rutherford, N. J., of coronary occlusion.
- Herman Frederick Thulin** * Denver; University of Nebraska College of Medicine, Omaha, 1900; on the staffs of St. Luke's Hospital, St. Anthony's Hospital, Mercy Hospital, Children's Hospital, Presbyterian Hospital, St. Joseph's Hospital and the Porter Sanitarium and Hospital; aged 62; died, October 17.
- Nels Christian Nelson** * Cheyenne, Wyo.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; for many years on the staff of the Laramie County Memorial Hospital; aged 66; died, October 15, in the Boulder (Colo.) Sanitarium of carcinoma of the pancreas.
- Ervin Lyman Matthews**, Morrilton, Ark.; University of Arkansas School of Medicine, Little Rock, 1908; member of the Arkansas Medical Society; past president of the Conway County Medical Society; served during the World War; on the staff of St. Anthony's Hospital; aged 54; died, October 17, of pneumonia.
- Frederick Gretton Brathwaite**, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; associate medical director of the Equitable Life Assurance Society; aged 71; died, October 30, in the Stamford (Conn.) Hospital of lobar pneumonia and myocarditis.
- Frederick Adrian Kinch** * Westfield, N. J.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1882; formerly secretary of the Union County Medical Society; president of the board of health; aged 79; died, October 25, of myocarditis and arteriosclerosis.
- Aloysius Robert Holdenried**, St. Louis, Mo.; St. Louis University School of Medicine, 1926; member of the Missouri State Medical Association; on the staffs of the Firmin Desloge Hospital, St. Mary's Hospital and the Deaconess Hospital; aged 38; died, October 14, of pulmonary tuberculosis.
- Albert Edwin Hayes** * Cranston, R. I.; Harvard Medical School, Boston, 1898; for many years on the staff of the Rhode Island Hospital, Providence; aged 72; died, October 26, at the Day Kimball Hospital, Putnam, Conn., of cerebral embolism and injuries received in an automobile accident.
- James Da Costa Highsmith** * Fayetteville, N. C.; Jefferson Medical College of Philadelphia, 1918; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; superintendent of the Highsmith Hospital; aged 49; died, October 18, of coronary occlusion.
- Edward Ludwig Paulsen**, Minneapolis; University of Minnesota Medical School, Minneapolis, 1909; member of the Minnesota State Medical Association; fellow of the American College of Surgeons; on the staff of the Deaconess Hospital; aged 56; died, October 7, of cerebral hemorrhage.
- Arley John Ostrander**, Cave Junction, Ore.; Minneapolis College of Physicians and Surgeons, Medical Department of Hamline University, 1908; on the staff of the Veterans Administration Facility; aged 59; died, October 15, of an accidental gunshot wound inflicted while cleaning a gun.
- Jacob Charles Rothenburg**, Springfield, Minn.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; member of the Minnesota State Medical Association; formerly on the staff of St. John's Hospital; aged 79; died, October 16, of coronary occlusion.
- Will H. Moore** * Valley City, N. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; past president of the North Dakota Health Officers Association; aged 63; died, October 20, in a hospital at Fargo.
- Julius Emanuel Isaacson** * New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1918; aged 44; served in various capacities on the staff of the Hotel Dieu, Sisters' Hospital, where he died, October 17, of coronary thrombosis.
- William Henry Forbes**, Poughkeepsie, N. Y.; Indiana Medical College, Indianapolis, 1877; Jefferson Medical College of Philadelphia, 1879; aged 88; died, October 5, in the Vassar Hospital of hypostatic pneumonia and traumatic fracture of the hip.

John Edward Farrell ☉ Waterbury, Conn.; University and Bellevue Hospital Medical College, New York, 1903; served during the World War; aged 62; on the staff of St. Mary's Hospital, where he died, October 30, of myocarditis.

Karl Fischel ☉ Saranac Lake, N. Y.; Medizinische Fakultät der Universität, Wien, Austria, 1901; superintendent and medical director of the Will Rogers Memorial Hospital; aged 62; died, October 29, of coronary occlusion and arteriosclerosis.

Wilson H. Thompson, Celina, Ohio; Marion-Sims College of Medicine, St. Louis, 1899; Cleveland University of Medicine and Surgery, 1901; member of the Ohio State Medical Association; aged 61; died, October 19, of cerebral hemorrhage.

Frederick William Edelmann, Saginaw, Mich.; Bellevue Hospital Medical College, New York, 1885; at one time city health officer; for many years police surgeon; aged 75; died, October 23, in St. Mary's Hospital of carcinoma of the larynx.

Theodore Grady Gaskins ☉ Mount Vernon, N. Y.; Medical College of Virginia, Richmond, 1929; on the staff of the Mount Vernon Hospital; aged 35; died, October 30, of an accidental gunshot wound inflicted while cleaning a gun.

Claude Bradbury Parker, Gallipolis, Ohio; Medical College of Ohio, Cincinnati, 1895; member of the Ohio State Medical Association; aged 65; died, October 30, in the Holzer Hospital of cerebral hemorrhage.

David Nathan Hopkins, Friendship, Ohio; Cincinnati College of Medicine and Surgery, 1898; member of the Ohio State Medical Association; aged 70; died, October 31, in the Mercy Hospital, Portsmouth.

Malcolm Lale Samms, New Orleans; Kentucky School of Medicine, Louisville, 1901; on the staff of the Veterans Administration; served during the World War; aged 62; died, October 30, of heart disease.

Clyde Jacob Munns ☉ Newburgh, Ind.; Kentucky School of Medicine, Louisville, 1908; county health officer; aged 54; died, October 24, in the Welborn-Walker Hospital, Evansville, of abdominal carcinomatosis.

Fannie Herriott Kellogg, New Rochelle, N. Y.; New York Medical College and Hospital for Women, 1882; aged 82; died, October 9, of cerebral hemorrhage, hypostatic pneumonia and arteriosclerosis.

Martha Bell Moorhead ☉ Minneapolis; Woman's Medical College of Pennsylvania, Philadelphia, 1892; an Affiliate Fellow of the American Medical Association; aged 73; died, October 13, of bronchopneumonia.

Carl Daniel Kolset, Sanborn, Minn.; Medical Department of Hamline University, Minneapolis, 1905; served during the World War; aged 63; died, October 18, of bronchopneumonia and chronic encephalitis.

Myer Mordecai Pinsky, Camden, N. J.; University of Maryland School of Medicine, Baltimore, 1925; member of the Medical Society of New Jersey; aged 38; died, October 6, of coronary thrombosis.

Eugene Ziegler Hillegass, Mantua, N. J.; Jefferson Medical College of Philadelphia, 1880; member of the Medical Society of New Jersey; aged 85; died, October 8, of coronary thrombosis.

John Joseph Dooling, Malverne, N. Y.; Long Island College Hospital, Brooklyn, 1899; surgeon to the police and fire departments; aged 64; died, October 3, of carcinoma of the lung.

Bertram A. Martin, Mineral, Ill.; Northwestern University Medical School, Chicago, 1893; aged 69; died, October 30, in the J. C. Hammond City Hospital, Geneseo, of heart disease.

Joseph B. Chambers, Los Angeles; Manitoba Medical College, Winnipeg, Man., Canada, 1898; aged 83; died, September 22, of arteriosclerosis, hypertension and cerebral hemorrhage.

Wallace Andrew Aitken, Enid, Okla.; Washington University School of Medicine, St. Louis, 1901; served during the World War; aged 62; died, October 15, of uremia and nephritis.

Thomas K. Shields, Wheeling, W. Va.; University of Maryland School of Medicine, Baltimore, 1890; aged 74; died, October 7, of chronic nephritis, myocarditis and arteriosclerosis.

Thomas Owen Crawford ☉ Dewey, Okla.; Denver and Gross College of Medicine, 1910; superintendent of health of Dewey; aged 66; died, October 20, of pneumonia.

William Henry Kendrick, Tulsa, Okla.; Hospital College of Medicine, Louisville, Ky., 1897; aged 77; died, October 22, of hypertension, myocarditis and cerebral infarct.

Jefferson Martain Colburn ☉ Riverside, Calif.; Kansas City (Mo.) Homeopathic Medical College, 1895; aged 81; died, September 15, of herpes zoster.

Avery Kirk Brodie, Derby, N. Y.; University of Buffalo School of Medicine, 1899; aged 66; died, October 4, of coronary occlusion and arteriosclerosis.

Richard Edward Banks, Washington, D. C.; Howard University College of Medicine, Washington, 1927; aged 50; died, October 16, of cerebral hemorrhage.

Alexander Curtis Elinor, McKenzie, Tenn.; Memphis Hospital Medical College, 1912; aged 64; died, September 15, of diabetes mellitus and hypertension.

George Frederick Martin, Corydon, Ind.; Hospital College of Medicine, Louisville, Ky., 1884; aged 80; died, October 20, of carcinoma of the stomach.

John Henry Martin ☉ Binghamton, N. Y.; University of the City of New York Medical Department, 1877; aged 85; died, October 4, of myocarditis.

Mary Sophia Ross, Hannibal, Mo.; Rush Medical College, Chicago, 1908; aged 72; died, October 5, in Central Bedeque, Prince Edward Island, Canada.

James Madison Godwin, High Point, N. C. (licensed in North Carolina, year unknown); aged 79; died, October 13, of carcinoma of the mastoid.

Thomas Martin Eaton, Viola, Tenn.; Vanderbilt University School of Medicine, Nashville, 1884; aged 84; died, October 4, of influenza and senility.

George Lounsbery, Huntington, W. Va.; New York Homeopathic Medical College, 1878; aged 84; died, October 13, of pneumonia.

William Edgar Hardman, Annona, Texas; Missouri Medical College, St. Louis, 1889; aged 78; died, September 14, of diabetes mellitus.

Zachariah Garton Jones, Downey, Calif.; Kansas City (Mo.) Medical College, 1905; aged 55; died, September 19, of angina pectoris.

Henry Edward Pastor, Petaluma, Calif.; California Medical College, Oakland, 1894; aged 83; died, September 28, of heart disease.

John Sutherland Douglas, Halifax, N. S., Canada; University of Toronto Faculty of Medicine, 1916; aged 46; died, October 26.

Harvey Almond Hill, Amarillo, Texas; Rush Medical College, Chicago, 1898; aged 66; died, October 25, of carcinoma of the liver.

Alma Kruemcke, San Antonio, Texas (licensed in Texas, under the Act of 1907); aged 69; died in October of cerebral hemorrhage.

Horace Cooper Wrinch, Vancouver, B. C., Canada; Trinity Medical College, Toronto, Ont., 1899; aged 73; died, October 19.

Correspondence

"CLINICAL GASTROENTEROLOGY"

To the Editor:—I wish to call attention to the review of my book "Clinical Gastroenterology," published in the September 2 issue of THE JOURNAL.

The reviewer states that "the text is amply illustrated. However, many of the x-ray films are obsolete, as evidenced by the presence of a ring to denote the position of the umbilicus on the plate. These, as the author does not state, are some of the older films of the late R. Walter Mills."

This statement is absolutely false for the following reasons:

On pages 60, 126, 150 and 240 it is definitely stated that the films are taken from Dr. Mills's original work.

On page 274 the films are taken according to Mills's original method of using small cylinder compression over the gallbladder region, and due credit is given him in the text.

Furthermore, I have never discontinued the use of the ring to locate the position of the umbilicus. This method is also being employed by many radiologists; therefore it is not true that the use of this ring indicates that the films are obsolete.

HORACE W. SOPER, M.D., St. Louis.

POLIOMYELITIS AFTER ADENOTONSILLECTOMY

To the Editor:—The subject of poliomyelitis following adenotonsillectomy is one of such importance that I submit the following tabulation of cases from the literature as a supplement to Dr. Felderman's letter in your issue of October 28. No case has been included in which the interval between operation and the onset of poliomyelitis was more than twenty-two days. The references will all be found in Stillerman and Fischer's paper (*Am. J. Dis. Child.* 56:778 [Oct.] 1938) except the one to the more recent paper of Koskoff, Amshel and Lebeau (*Arch. Pediat.* 56:19 [Jan.] 1939). The recent cases reported by Ayer and by Aycock are mentioned by Stillerman and Fischer as obtained by personal communication:

	Cases	Bulbar
Ayer (1928)	9	9
Aycock and Luther (1929)	16	11
Silverman (1931)	5	4
Stillerman and Fischer (1938)	13	9*
Aycock (1938)	2	2
Ayer (1938)	6	6
Eley and Flake (1938)	20	17
Koskoff, Amshel and Lebeau (1939)	2	2
Total	73	60 (82%)

* Including two cases of encephalitis.

As Stillerman and Fischer point out, the proportion of bulbar cases in poliomyelitis after adenotonsillectomy is so much higher than in poliomyelitis generally that the chances of its being accidental are statistically negligible (fifteen in 10,000 in their own series, in which the proportion is lower than in the totals of the compilation given in the tabulation). There seems to be little doubt that the operation provides a portal of entry through the traumatized cranial nerves supplying the tonsillar fossa and the nasopharynx to virus already present in that region. The studies of A. B. Sabin (Experimental Poliomyelitis by the Tonsillopharyngeal Route, *THE JOURNAL*, Aug. 13, 1938, p. 605) give experimental support to this contention.

HAROLD K. FABER, M.D., San Francisco.

LOST PATIENTS FROM AN OUTPATIENT CLINIC

To the Editor:—In *THE JOURNAL* of September 9, page 1037, appeared an article captioned "Lost Patients from an Outpatient Clinic" by Horace Gray, M.D., and Margaret Curtis, R.N. The report was made to determine the percentage of patients who could be persuaded to return to the clinic. The follow-up mailing system was used for this purpose.

The summary showed that the "clinic fails" amounted to 14 per cent, and the writers bemoaned the fact that from the point of view of social economy the results were most discouraging. Is it possible that the time spent by the clerical force on these patients is stretching the humanitarian purposes of dispensary work too far? This leads me to answer in the affirmative. Moreover, the present social system has a tendency to humor patients, often leading them to believe that the benefits derived are wholly shared by the dispensary physicians. In this assumption the outpatient patrons cannot be entirely blamed. The social service department, to justify its existence, must necessarily encourage a large active attendance of outpatients. The social worker makes it a point to cater to the whims of the patients in the same manner that a manager does to a temperamental metropolitan opera star.

I have had twenty years of clinical work and in my experience patients who apply for free treatment are those who feel that the best specialists can be found in hospitals. Moreover, they are under the impression that dispensary physicians are paid officials.

There are many reasons why patients fail to return to the clinic. First, the economic status of the family might have improved—a fact not disclosed in the follow-up system of Gray and Curtis. Of course lame excuses such as that the patient could not wait, that home duties interfered with treatment or that their automobile was not in working condition are but a few that account for the clinic "fails."

It would be considered somewhat gauche from an ethical point of view if a physician were to write a letter to his private patient asking him why he did not return for treatments. The patient would question the motive and his suspicions would be unduly aroused. The same sort of reasoning prevails with clinic patients.

Of course, ambitious social service workers and superintendents of hospitals devise ways and means of writing to patients so that the roll of clinic admissions can be lengthened. The same group has inspired the story about hospital costs and inadequate care of the sick in this country.

Some of the physicians engaged in the dispensary work feel that if the superintendents or social workers had their way they would install private cubicles for patients and have them enter or leave the place in some sort of disguise so that they would not be recognized. It has also been suggested that patients who are great lovers of music should have some sort of symphonic entertainment while waiting for treatment. It would help to chase away the tedium of monotony. Motion pictures too have their place.

I believe that the selfless idea of free treatments in the outpatient departments is overstressed, and physicians are opposed to have these patients brought back by postcard or telephone, no matter how scientifically interesting their conditions may be.

I strongly believe that 60 per cent of the patients admitted to the dispensary can well afford private treatment and that by crowding out the 40 per cent who are deserving of free treatments and who require no reminders they are jamming up the hospital machine.

If it is not ethical for a physician to solicit a patient, neither should it be the prerogative of a social worker to coax patients back to the outpatient clinic.

LEON FELDERMAN, M.D., Philadelphia.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CHOICE OF TREATMENT IN PNEUMONIA

To the Editor:—About two years ago a woman aged 62 had pneumonia of the right lower lobe. Because of lack of typing facilities she was given combined types I and II serum and also sulfanilamide totaling about 30 Gm. After about five days she complained of pain in the right upper quadrant and over the liver and lower part of the chest. Jaundice then appeared, and it was felt that she had hepatitis. Sulfanilamide as the cause was questioned, first because of the small total dose and second because of previous gallbladder (and liver?) dysfunction. Furthermore the pneumonia, which was in the right lower lobe, might have been contributory. After prolonged dextrose and oxygen therapy she recovered. Later she proved to have had type VII pneumonia. My questions are: 1. If this patient contracts pneumonia again, what would be the choice of treatment; sulfapyridine or serum? 2. Is it not true that she may now be sensitive to both? 3. Would there again be danger of hepatitis? 4. Has serum proved to be efficacious in elderly persons? 5. Do not most authorities, thus far, feel that sulfapyridine is, in such cases, apt to bring better results?

M.D., Iowa.

ANSWER.—1. The choice of the appropriate specific treatment for a patient suffering from pneumococcal pneumonia depends on such factors as the condition of the patient's liver, kidneys and blood-forming organs, the type of pneumococcus involved, the time of treatment and the presence of bacteremia, as well as the availability of remedies and of the skills required to use them effectively. All the indications and contraindications for the several available remedies have not been established. Patients suffering from the type III pneumococcus, especially with bacteremia, should receive sulfapyridine. Patients in the early stage of pneumonia of a type for which potent serum is available, if they are insensitive to the kind of serum to be employed, and patients who have failed to produce immunity as evidenced by the spread of the lesion may receive both serum and sulfapyridine advantageously. In the absence of contraindication, sulfapyridine may be given pending the report on laboratory work.

2. It does not follow from her experience that this patient is sensitized to either remedy, sulfapyridine or serum. Sulfapyridine sensitivity is probably not acquired from previous use but is due to vulnerability of tissues. If tissues have been severely injured by a previous administration, it is well not to give the remedy a second time. Patients are not necessarily sensitized by serum and, if sensitized, do not necessarily retain their sensitization for two years after the administration of either horse or rabbit serum. If the patient has become sensitized to a serum, serum from a different animal source may be employed or, if necessary, even from the same source by the method of inducing a refractory phase and antianaphylaxis, described by J. G. M. Bullowa (*The Management of the Pneumonias for Physicians and Medical Students*, New York, Oxford University Press, 1937, p. 309). There is no evidence that sulfanilamide sensitizes patients to sulfapyridine or that sulfapyridine cannot be used advantageously in a second attack of pneumonia after the first has been treated with that drug.

3. There is insufficient evidence presented for one to assert that this patient had hepatitis. Some hepatic damage may have resulted from the use of sulfanilamide or from her disease, or there may have been simultaneous cholelithiasis. It would be helpful to know the depth of the jaundice or whether blood phosphatase was increased.

4. Ample early doses of specific serum have been efficacious in the treatment of old persons suffering from pneumococcal pneumonia.

5. Some authorities feel that both serum and sulfapyridine should be used in the severe infections of old persons unless there is a specific contraindication for one or the other. Recovery from pneumonia ultimately depends on the operation of immunity factors, and in older persons the immunity mechanism may be feeble. Serum hastens the advent of an excess of antibody, which is required to neutralize specific capsular carbohydrate and to induce both phagocytosis and lysis. Sulfapyridine inhibits or kills pneumococci, provided an adequate concentration for the pneumococcus present is maintained for a sufficient length of time. The use of serum with sulfapyridine decreases the amount of sulfapyridine and of serum required. Old persons may suffer from azotemia after dosage with sulfapyridine because they frequently have impaired kidneys. Bone

marrow function, which is often feeble in the elderly, may be further depressed. No one has had sufficient controlled experience to be authoritative in expressing a preference for either type of treatment in the elderly as opposed to those in other periods of life.

BLOOD SEDIMENTATION

To the Editor:—What is the simplest blood sedimentation test, what technique is used and what are the normal readings? Does it make any difference whether sodium citrate solution 5 per cent or ammonium oxalate with potassium oxalate is used as long as the blood is prevented from coagulating? Why are both the ammonium and the potassium oxalate used? Would not one of them be enough? Is not use of Wintrobe hemocrit with one of the coagulants as simple and accurate as the Westergren method?

M.D., Minnesota.

ANSWER.—There is some difference of opinion regarding blood sedimentation tests. One of the simplest certainly is the Linzenmeier test. Linzenmeier tubes with calibrations at the 0, 6, 12 and 18 mm. levels are easily procurable and cheap. One and six-tenths cc. of blood drawn from the vein is mixed with 0.4 cc. of 3.8 per cent sodium citrate solution in a small medicine glass or evaporating dish and the tube is filled with the mixture to the 0 mark and allowed to stand upright in a small rack. For women from two to five hours is required for the blood to fall to the 18 mm. level. For men the time required is from three to seven hours.

With regard to the use of anticoagulants, experimental work has shown that sodium citrate solutions in the concentrations used with the Linzenmeier and Cutler techniques retard the sedimentation rate considerably. It has been found that the ammonium oxalate and potassium oxalate mixture as devised by Heller and Paul has no effect on sedimentation rate or erythrocyte cell volume. Potassium oxalate in 20 per cent solution may be used alone as the anticoagulant without producing any significant alteration of the sedimentation rate.

Use of the Wintrobe hemocrit with the mixture of ammonium and potassium oxalates as the anticoagulant would probably be as simple and as accurate as the Westergren method.

ANAPHYLACTIC REACTIONS AND HORSE SERUM

To the Editor:—I am writing to ask your advice as to the quickest and simplest method for skin testing children before administering horse serum. As part of my work as city physician I treat a number of cases of diphtheria, in most of which toxoid has been previously administered. Consequently the diphtheria is quite mild. On occasions I have used an intradermal test with a 1:10 dilution of the serum and have then waited twenty minutes for a reaction. This procedure is time consuming because the syringes in which our antitoxin is supplied have needles which are too large for intradermal use. Consequently it is necessary to sterilize a hypodermic syringe to perform this test. On other occasions I have simply placed one drop of undiluted antitoxin in the conjunctival sac. I have serious accidents ever been known to follow administration of horse serum when the conjunctival test was negative? 2. What test for sensitivity would you recommend under the circumstances mentioned?

M.D., Virginia.

ANSWER.—1. Yes, instances have been recorded in which death resulted from anaphylactic shock following the administration of horse serum to patients whose conjunctival tests for sensitivity had been negative. Unfortunate occurrences of a similar nature have also taken place notwithstanding that intracutaneous sensitivity tests to horse serum were negative.

2. The intracutaneous test for sensitivity which has been used is the one most commonly employed. When the ophthalmic test is performed a dilution of 1:10, as in the case of the intracutaneous test, is perhaps preferable to using undiluted serum. Sometimes a scratch test is made for the purpose of indicating susceptibility to horse serum. For practical purposes, under the conditions described, a scratch test might be sufficient.

As toxoid contains no horse serum and because toxin-antitoxin is used much less frequently than some years ago, it might be expected that fewer serum reactions would result than formerly. On the other hand, because of an increased use of scarlet fever antitoxin a certain number of children may have been sensitized to horse serum on that account. With the improved methods of concentration and refinement, antitoxin serum reactions seem to be much less numerous and far less severe than many years ago.

In some contagious disease hospitals, routine sensitivity tests are made on all patients to whom serum is to be administered. In other contagious disease hospitals no tests are made for sensitivity unless a history of previous serum administration has been obtained or some allergic condition is known to exist. In two contagious disease hospitals in which the latter plan is followed, many thousands of diphtheria patients have been treated without a single instance of an anaphylactic death.

CHLORAL HYDRATE AND WHISKY

To the Editor:—I recently read in Bastedo's *Materia Medica*, 1938 edition, that chloral hydrate should never be given with alcohol. A patient, after trying everything, gets more satisfaction from 2½ drachms (9.5 cc.) of a chloral preparation at 9 p. m. and 1½ ounces (45 cc.) of whisky in a tumbler of water at 10 o'clock. Is there anything in Bastedo's remarks as quoted that would apply to this? The patient never has to take anything for asthma during the day, but most nights one or two such doses between 10 p. m. and 6 a. m. For ten years he relied on epinephrine.

Nathaniel F. Cheever, M.D., Greenfield, N. H.

ANSWER.—Chloral hydrate should never be administered with alcohol in a prescription. The combination of chloral and alcohol results in the formation of chloral alcoholate, which used to be known as "knock-out drops" and is now termed a "Mickey Fina." Chloral alcoholate is a powerful and rapidly acting cerebral depressant. In prescriptions containing chloral and alcohol, the chloral alcoholate tends to rise to the surface. Without the proper shaking, the danger of acute intoxication from such a preparation is immediately apparent, since the patient receives all of the chloral at the first dose. The preceding remarks do not necessarily apply, however, to the conditions stated in the question. The patient is taking single doses of chloral hydrate with whisky, and the result is better hypnosis and deeper depression. The patient evidently requires this amount of depression to sleep in spite of his asthma and the only harm that can result will be the possible damage to the liver and other parenchymal tissues from the use of chloral hydrate and alcohol.

MIGRAINE

To the Editor:—A 50 year old white man for the past twenty years, with increasing frequency, has had attacks beginning with central blurred vision in the left eye, spreading peripherally and followed almost immediately by similar haziness in the right eye. Vision clears from right to left, completely leaving the right eye first and the lateral half of the left eye last. This phase always lasts exactly twenty minutes and is followed by pain behind the eyeballs which may last anywhere from one to twenty-four hours. The attacks occur at any time of the day, and the patient has even awakened in the morning with typical pain behind the eyeballs. Occasionally the attacks are accompanied by numbness of the hands, lips and tongue. Competent ophthalmologic examination reveals only a slight degree of sclerosis. Routine physical and neurologic examinations show no abnormality. The history is negative for head injury, and there is no family history of migraine, epilepsy or similar disorder. The patient is overweight, and three of his four children show varying degrees of Fröhlich's syndrome. What procedures should be adopted to establish a diagnosis?

M.D., Ohio.

ANSWER.—The diagnosis must be based on the history, as structural changes are unlikely to be found by roentgenograms or even by encephalogram or ventriculogram. The long history, sudden onset of the central scotoma, rapid course, pain behind the eyes, paresthesias of hands, lips and tongue and complete recovery from each periodic attack are typical of migraine. The lack of abnormal ophthalmologic features, absence of family history of migraine or epilepsy and signs of endocrine dysfunction in the children are also consistent with the diagnosis, although a large percentage of patients with migraine have a family history of attacks. Similar cases of migraine will be found in the classic descriptions of the disease as given by Airy, Living and others.

PASSIVE VASCULAR EXERCISE

To the Editor:—What information can you give me on the present status of passive vascular exercise or other pressure-vacuum devices for the improvement of the circulation in arterial occlusion? Are any such devices Council accepted? What recent articles have appeared on this subject?

M.D., Minnesota.

ANSWER.—There is a wide difference of opinion relative to the clinical value of passive vascular exercise, a term used to designate alternate periods of suction and pressure applied to an extremity enclosed in some device such as a glass boot. Several such devices are accepted by the Council on Physical Therapy. The evidence that passive vascular exercise significantly increases the circulation to an extremity lacks impressiveness. In fact, there is no conclusive physiologic evidence that the circulation is improved. In spite of this, some physicians who have had wide experience with this method of treatment feel that definite clinical evidence of improvement in the circulation of persons suffering from arterial diseases results from it. Other physicians feel that the benefit noted does not result specifically from this particular treatment but that it is due in large degree to other methods of treatment carried out at the same time and to

natural processes of healing and to establishment of collateral circulation. Some physicians believe that passive vascular exercise is valueless. A fair summary of the situation is that the earlier enthusiasm for this treatment has subsided greatly.

URINARY SEDIMENT

To the Editor:—For some time I have been seeing a peculiar sediment in the urine which I cannot identify, and I find no reference to it in any laboratory manual available. It is "black" masses of what appears to be pigment matter, not unlike the calcium bilirubinate pigment in bile. I found them in unusual numbers recently in a specimen showing heavy calcium output with Sulkowich reagent. Examination of the calcium sediment still showed a moderate number of these masses. Could they be calcium and therefore indicate excessive calcium elimination?

S. R. Salzman, M.D., Toledo, Ohio.

ANSWER.—It is almost impossible to give a definite reply as to the character of the "black masses." It might be discolored tyrosine. If so, it should be soluble in dilute alkaline or dilute sulfuric acid solutions. Such solutions, if not too weak or too acid or basic, should give a positive Millon reaction. The black masses might also be melanin. If so, one would expect the urine to be highly colored. The material should be somewhat soluble in alkaline solutions and should then be reprecipitated as brown to black material on addition of acid to the neutral point or slightly beyond. If a few drops of ferric chloride solution added to 100 cc. of urine produce a gray precipitate which darkens on addition of more ferric chloride, it is considered a positive test for melanin. Melanins should not be confused with indigo. If the dark masses are due to indigo, the material should dissolve in chloroform.

VERTIGO

To the Editor:—A patient's chief complaint is vertigo. A few nights ago she awakened to find herself extremely weak, nauseated and dizzy. She turned on the light and attempted to get out of bed, but the vertigo was so severe she was forced to lie down. She described the sensation as feeling "like the room was spinning around." She was so weak that it was an effort to lift her hand. She was given a small drink of whisky and shortly thereafter went to sleep. The next morning she apparently was all right until she got out of bed and walked a short distance, when the vertigo returned again and she had to hold to the wall to keep from falling. She was helped back to bed and after lying down a while felt all right again. The next day while lying on my examining table she suddenly grasped the table and became much alarmed. She said "something like a wind" had passed through her head in the occipital and mastoid regions, and the vertigo had returned again. She had no ringing in the ears and was not worse on lying on either side. This vertigo continued when the patient was in the erect position for twenty-four hours and then began to subside (during this time the patient was in bed) only to return again when she was up for several hours. Results of physical examination were negative except for a pulse rate of 54 per minute. This increased to 90 per minute during the attack. The blood pressure is 120 systolic and 78 diastolic. The urine and blood counts are normal. A blood Wassermann test is being done. Examination by a nose and throat specialist shows no abnormality except a minor error of refraction. Examinations to determine the condition of the labyrinth were not done. There is no nystagmus. This is apparently a case of pseudo Ménière's disease. I am considering the possibility of brain tumor. What other procedures may be done to make the diagnosis more definite? I have put the patient on a salt-free diet and am administering rather large doses of ammonium chloride. I should like advice on the treatment of such a condition and the prognosis as far as is known.

M.D., Georgia.

ANSWER.—True vertigo always indicates a disturbance of the labyrinth. Such disturbances may be transient functional affairs, organic disease in the labyrinth itself, disease of the nerves such as Ménière's syndrome and disease of the central nervous system at higher levels. Ménière's disease produces vertigo but this diagnosis cannot be safely made from the data given here, although the possibility should be thoroughly investigated. Brain tumor is another possibility.

The treatment of this condition must be based on more accurate diagnosis, and no prognosis can be hazarded until such a diagnosis is made. Tests to determine the cause of vertigo and to localize such causes constitute a rather highly specialized procedure and require an intimate knowledge of cerebral localization. A discussion of this subject, with references to original sources, may be found in most standard textbooks on neurology. Two such works are:

- Wechsler, I. S.: *A Textbook of Clinical Neurology*, Philadelphia, W. B. Saunders Company, 1935.
Grinker, R. R.: *Neurology*, Springfield, Ill., Charles C. Thomas, Publisher, 1934.

VISUAL DISTURBANCE AND SULFANILAMIDE

To the Editor:—A white man aged 33 had gonorrheal urethritis and cystitis. Besides the usual local treatment I prescribed sulfanilamide 2.4 Gm. daily for the first week and 1.8 Gm. for the second week. After that time the patient suddenly complained of visual disturbances, which made it impossible for him to drive his car. He was able to read a newspaper when it was brought near to his eyes. There was no headache or any other pain. The next day he had a temperature of 100.4 F. and a skin rash, limited to the face and forearms, which had been exposed to sunlight. The eye examination by an ophthalmologist revealed a definite myopia, which could be completely corrected by means of glasses. There was no ciliary spasm or optic neuritis. Sulfanilamide was interrupted and after five days the patient's eyesight was normal again. He never stopped working. Since I have not found a similar case in the literature concerning sulfanilamide I should like to know whether such a symptom has been observed before.

Manfred Landsberg, M.D., Cudahy, Wis.

ANSWER.—Instances of disturbances of vision in the course of sulfanilamide therapy are quite uncommon. Many patients may complain of difficulty in reading during sulfanilamide therapy, but this in general is due to an inability to concentrate well rather than to any disturbance in vision.

Paul C. Bucy (Toxic Optic Neuritis Resulting from Sulfanilamide, *THE JOURNAL*, Sept. 25, 1937, p. 1007) reported that a girl with osteomyelitis developed severe disturbances in vision because of a toxic optic neuritis after the administration of a single tablet (0.3 Gm.) of the drug. Four days elapsed before the child's vision was normal. Visual hallucinations have been noted. Temporary myopia has not been described.

FULGURATION OR DESICCATION OF MOLES

To the Editor:—Apropos of the query "Moles and Their Excision" in *The Journal*, September 16, page 1152, I should like to inquire as to the propriety of removing the moles, particularly the deeply pigmented ones, by means of fulguration, or desiccation. Women particularly are anxious and willing patients for the cosmetic improvement obtained, and while I have had excellent results so far, the thought of malignancy always obtrudes. Naturally, with the high frequency currents the tissue is totally destroyed (sufficiently beneath the corium), making pathologic study obviously impossible. Excision would leave scars. M.D., New York.

ANSWER.—The question of fulguration, or desiccation, of pigmented moles is to some degree controversial. Many physicians are of the opinion that this procedure is effective and without danger. This opinion is based on the treatment of large numbers of lesions by such methods without apparent complications. Another school believes that desiccation, or electrocoagulation, of pigmented moles is accompanied by the possibility of dissemination of the disease. This opinion is based on the clinical observation of patients who have been treated in this manner and who developed fully malignant melanomas in the treated areas. Numerous authorities on this question are of the opinion that the safest therapeutic procedure for a pigmented mole which is subjected to irritation or which is showing changes suggestive of malignant degeneration is careful, wide surgical removal.

TIGHT FORESKIN AND CIRCUMCISION

To the Editor:—In the newborn male child what is the best method of dealing with a tight foreskin of the penis? Is circumcision or just nicking, thus retracting it, the best measure? M.D., Pennsylvania.

ANSWER.—It is generally considered that the tight foreskin at birth may be safely let alone provided there is ample room for urination. If it is necessary because of blockage of the stream to make an opening, this can be done by breaking up the adhesions and retracting the foreskin or by circumcision, the choice of which procedure should rest with the family.

In most instances with tight foreskin if the physician and mother will be patient, retraction can be done after several months as a gradual procedure without any operation at all.

NITRAZENE TEST OF SALIVA

To the Editor:—Of what value is the nitrazene test of saliva in determining the body pH? Dr. Walter B. Guy, of Florida, suggests using a cantharides plaster for eight hours and then determining the pH from the plasma by means of phenol red. In making this test is it the aqueous or the alcoholic phenol red which is used as the indicator? Is there any special color chart to use? How reliable is this test?

Henry B. Hibbe, M.D., Dubuque, Iowa.

ANSWER.—The nitrazene test is a rough test for the pH of body fluids. The phenol red test, if properly applied, is more accurate. The phenol red solution is prepared by grinding in a mortar 0.03 Gm. of pure dye with 0.86 cc. of tenth normal sodium hydroxide and diluting the final solution to 100 cc. with distilled water. To apply the test, collect about 5 cc. of saliva by

expectorating into a test tube containing 2 cc. of neutral liquid petrolatum. Take 4 cc. of the saliva and add 0.2 cc. of the phenol red indicator solution. It is best to compare the color with standards of different pH values containing the same amount of phenol red. A color chart is published by William Clark in his *Determination of Hydrogen Ion Concentration*.

LUDWIG'S ANGINA

To the Editor:—Is there any evidence that Ludwig's angina ever assumes epidemic proportions? Particularly in the experience of the late World War was it more common except in the presence of oral injuries? In operating room technic is it considered more infectious than the ordinary pyogenic infections? M.D., Pennsylvania

ANSWER.—No evidence has been found that Ludwig's angina ever assumes epidemic proportions. While cervical cellulitis was common in the World War, Ludwig's angina was not and did not commonly complicate oral injuries. The causative organisms vary and are not regarded with any more concern in the operating room than any other acute infection.

NO HEREDITARY FACTOR IN FACIAL PARALYSIS

To the Editor:—A 35 year old housewife has a right peripheral facial paralysis. The etiology has been determined as exposure to an open window. The patient's father and older brother at one time in their lives also had attacks of peripheral facial paralysis. Can you tell me whether there is a form of familial peripheral facial paralysis and, if there is, can you tell me where I can find the articles describing it? M.D., New York.

ANSWER.—It is not believed that the facial paralysis in such cases has anything to do with familial periodic paralysis or any other familial disease. The disorder is so common that it might easily happen to affect several members of a family.

FEVER FOR BRONCHITIS AND ASTHMA

To the Editor:—Would fever cabinet treatments be of any value in chronic bronchitis and asthma? Has sulfanilamide been used in this condition. M.D., Illinois.

ANSWER.—The fever treatment for asthma was tried originally for severe intractable cases. Even for these, it has now been generally discarded as too severe a form of management for the results obtained. Sulfanilamide has not been tried for this condition. There seems to be no adequate basis for its trial.

WOOL SENSITIVITY IN WOOLEN INDUSTRY

To the Editor:—Do you know of any particular treatment the woolen manufacturers use on their employees that are allergic to wool? M.D., Michigan.

ANSWER.—The only two methods that can be used in wool sensitive cases are avoidance of contact or minimizing contact with virgin wool, and hyposensitization. The former is far preferable to the latter. It is hardly possible to decrease the amount of wool dust in wool manufacturing establishments. No information on a successful means used in wool sensitive patients who are compelled to remain in the industry has been found.

FELIX VI SERUM FOR TYPHOID

To the Editor: The phrase "Felix Vi serum against typhoid" has come to my attention. Any information you can give me on this item will be appreciated. D. Paul Ward, M.D., Fort Ontario, N. Y.

ANSWER.—Felix believes that one of the important components of the typhoid organism is the Vi (virulence) antigen. He has prepared an antiserum rich in Vi antibodies which he suggests for therapeutic and prophylactic application.

So far as known this serum is not commercially available in this country and is still in the experimental stage.

ZINC OXIDE INTRARECTALLY

To the Editor:—Can there be any deleterious results from using official zinc oxide intrarectally daily for chronic proctitis? M.D., Illinois.

ANSWER.—In considering any possible deleterious effects from the daily use of zinc oxide intrarectally, the local and possible systemic effect must be considered. Owing to its insolubility under the conditions mentioned, the degree of absorption of zinc oxide is practically nil. There is little likelihood of systemic or harmful local effects when zinc oxide is used for its soothing and protective action.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 12-14. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Written. Part I. Various places throughout the United States and Canada, March 28. Oral. Part II. New York, June 10-11. Applications must be received 60 days prior to examination. Sec., Dr. Paul N. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF SYPHILOLOGY: November 1940. If sufficient are received before March 1, June 10-14. Sec., Dr. C. Guy Lane, Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: General oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Written. Various cities of the United States and Canada, March 2. (The only written examination in 1940.) Oral. New York, June 8-10. Formal applications must be received before Jan. 1. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 3-5. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: New York, June 10-11. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics, Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 18-19. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington D. C.

California July Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at San Francisco, July 11-13, 1939. The examination covered nine subjects and included 90 questions. An average of 75 per cent was required to pass. Two hundred and fifteen candidates were examined, 204 of whom passed and eleven failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)		83.2.
85.8, (1939) 75.1, 75.9, 75.9, 76, 76.1, 78.8, 79.2, 79.7, 79.7, 79.8, 81.1, 81.2, 81.8, 82.4, 82.9, 82.9, 83.3, 83.8, 84.6, 84.8, 84.8, 85, 85.1, 85.8, 85.9, 87.3, 88.7

Book Notices

Public Health Law. By James A. Tobey, Dr.P.H., LL.D., Lecturer on Public Health Law at Harvard University School of Public Health, Boston. Second edition. Cloth. Price, \$3.50. Pp. 414. New York: Commonwealth Fund; London: Oxford University Press, 1939.

This edition of Public Health Law is much more comprehensive than the author's earlier volume and has been completely rewritten. The volume is a modern textbook on the important phases of the laws of public health. The publication, therefore, should find importance to those concerned in the various phases of public health and its administration. The text is divided into four major portions, on public health law and administration, the powers and duties of health departments, liability, which includes a thorough discussion of personal liability of health officers, and legislation and law enforcement. Under these four major headings, public health law is discussed in a simple and interesting manner. At the same time there is very little personal opinion of the author. The text is based on facts and references to higher court decisions. Because of the importance of a thorough knowledge of public health law and all its phases to health officers, students of public health, physicians, judges, attorneys, government officials and others, a selected bibliography on public health administration and legal aspects of public health has been gathered by Dr. Tobey. Occasionally public health officials who have been attempting to discharge their duties conscientiously and impartially are distressed to find themselves confronted with indictment or injunction proceedings. Defenses against these legal actions not only are time consuming but may interfere with the proper conduct of official duties and are often unnecessarily expensive. It is highly important, therefore, that health officials discharge their duties with the minimum of litigation either by or against them. Of course there are occasions when court action is necessary as a last resort. For such occasions the wise health official will be amply prepared not only by his conduct but by his familiarity with legal principles applicable to public health. This book may help him attain such familiarity.

The Principles of Dental Medicine: The Medical Aspects of Dental Disease. By F. W. Broderick, M.R.C.S., L.R.C.P., L.D.S., Hon. Dental Physician to the Royal Victoria and West Hants Hospital, London. Third edition. Cloth. Price, \$7.50. Pp. 575, with 44 illustrations. St. Louis: C. V. Mosby Company, 1939.

A fool is bent upon a twig, but wise men dread a bandit.
Which I think must have been clever, for I didn't understand it.

This quotation, taken from the review (*Bristol M.-Chir. J.* 53:114 (summer) 1936) of the Common Cold and Influenza by J. E. R. McDonagh, may with equal aptitude be applied to Broderick's book. The latter has based his text largely on the theories and terminology of McDonagh, both of which are so unusual that the reader has to acquire not only new definitions for words commonly used by physicians, physiologists and biochemists but also an entirely new theory for the mechanism of disease. No doubt most of those who read it will label it "clever," though probably because they don't "understand it." The arrangement is faulty, there is a great deal of repetition, and quotations from other authors are overnumerous and many inept. McDonagh and Broderick's notions are summed up in the latter's statement "Disease being, as we have seen, primarily the consequence of the condensation of one protein particle by another, in the process of which the less condensed is robbed of electrons by the more condensed, it depends essentially on the existence of a state of colloidal disequilibrium." Dental caries, Broderick believes, is due to pure dehydration (acidosis, agglutination) of the colloidal protein particles of the blood plasma and pyorrhea to pure hydration (alkalosis, dispersion). It should be noted that he uses such terms as hydration and dispersion in special senses quite different from conventional practice. Gingivitis is the result of colloidal disequilibrium between dehydration and hydration and a connecting link between pyorrhea and caries. The extreme degree to which such ideas have been carried by him is illustrated by the following: "Another factor which needs mention is that of masturbation, a circumstance which may definitely play a part in the production of dental caries through metabolic upset in the direction of an acidosis." The book is divided into three parts: part I, general physiologic

considerations, treats of such subjects as acid-base balance, vegetative nervous system, endocrine system, colloidal state, calcium metabolism, saliva, nature and cause of disease; part II, dental medicine, including etiology and prevention of caries and pyorrhea, action of drugs, aim of medical treatment, experimental methods; part III, relation of dental to general medicine, covering effect of civilization, effect of dental sepsis, teeth in arthritis, allergic disease, tuberculosis, malignant disease, diabetes and pregnancy. The formal text is concluded by the introduction of twenty-five case histories illustrating the author's methods of diagnosis and treatment.

Le cancer de l'estomac au début: Étude clinique, radiologique et anatomo-pathologique. Par René-A. Gutmann, médecin des hôpitaux de Paris, Ivan Bertrand, directeur à l'École des Hautes Études, et Th. J. Péristhany, assistant à la consultation de gastro-entérologie de la Salpêtrière. Préface du Dr A. Gosset. Cloth. Price, 360 francs. Pp. 493, with 563 illustrations. Paris: G. Dolin & Cie, 1939.

There is an introduction by Prof. Antonin Gosset. This publication is the only one of its kind dealing exclusively and extensively with gastric cancer in its earliest stages. The appearance of such a work is extremely welcome not only because of the importance of the subject matter but because of the enviable reputation of the senior author, an experienced and skilful gastro-enterologist. For serious students of the clinical and radiologic aspects of gastric disease an English translation is highly desirable. The subject matter is arranged in the following order: clinical 111 pages, radiologic 170 pages, methods of laboratory examination thirty pages, treatment ten pages, and gross and microscopic pathology 150 pages.

Gutmann and his collaborators emphasize the important fact that any gastric disorder of recent onset which is of a persistent nature and recurs should be considered as serious until proved otherwise. They describe three clinical types of gastric carcinoma: latent, painless and painful. Clinicians will heartily approve the strong emphasis placed on the observation that the symptoms and signs of early carcinoma are often lacking, trivial or distorted. Included in the first type are patients with a symptomless epigastric tumor or with such initial symptoms as edema or those engendered by metastases. The second type may be characterized by nothing but a vague indigestion, which may at the outset be temporarily relieved by treatment, or by such symptoms as anorexia, nausea, vomiting, dysphagia, acrochagia, hemorrhage, hunger pain, constipation, diarrhea, fever or loss of weight or strength, any one of which, or a combination of which, may be the initial and exclusive complaint. The painful form has its origin in ulcer-like cancer (le cancer ulcéreux), cancer on ulcer (l'ulcère transformé) and a third form designated le cancer gastrique muco-érosif à marche lente. This is a rare superficial variety with ulcer-like symptoms of long duration, not of progressive severity, which may remain localized to the mucosa for a long period. The aforementioned three types are illustrated by short case histories.

The authors have also had the experience that malignant ulcers may appear to heal, or be temporarily healed, under medical treatment. To show how frequently one sees early ulcer-like lesions, Gutmann and his co-workers (page 52) state that during the last 300 gastrectomies performed in their clinic there were removed eighty-five ordinary vegetative cancers, 133 benign ulcers, forty-three ulcers which had apparently begun benignly and then later became malignant, and thirty-nine ulcer-like cancers.

From a roentgenologic standpoint early gastric cancer consists of three general forms: infiltrating, ulcerating and tumefactive (formes végétantes). The former is characterized by the presence of localized regions of rigidity, by cone shaped or pencil point defects of the pylorus, by "aspect encastré" or by undulating or lacunar forms of filling defects. The ulcerating form is characterized in order of importance by the niche en plateau, an elevated defect in contrast to the depressed or dish-like image encastrée, by the large triangular niche, by the niche encastrée, and by the meniscus sign (la niche à ménisque). Contrary to what is generally believed, the authors think that the last mentioned sign is not pathognomonic for cancer and that it should be interpreted with caution because, in their opinion, this sign may be produced by periulcerous inflammatory changes. One procedure which appears logical to the clinician, and which should be employed more often by the radiologist, is the routine

treatment of these patients for from four to six weeks and reexamination thereafter. The effect of such treatment often appears decisive in arriving at a final diagnosis in these early lesions.

In the authors' opinion it is not possible to make a diagnosis of incipient carcinoma by the gastroscope; gastric analysis is of no help in the diagnosis of early cancer; though decidedly inferior to roentgenologic examination, the systematic examination of the feces for occult blood is more important than the other methods; serologic and cytologic studies are of no value in the diagnosis of early cancer; the classic chronic gastritis is not considered the precursor of cancer, although there may be a gastritic stage of incipient cancer; there appears to be no justification for gastric resection for gastritis in order to avoid gastric cancer.

The section on gross and microscopic anatomy of the disease is highly instructive and convincing, and the illustrations are numerous, ample and clear. As a matter of fact, the illustrations throughout the book are all that one could desire.

To many roentgenologists the section on roentgenologic diagnosis may prove disappointing, chiefly because the value of roentgenoscopy, study of the mucosal relief and the significance of the meniscus sign are belittled. On the contrary, a study of the barium-filled stomach is extolled. Granting that the authors' method of examination and interpretation may result in early diagnosis of early cancer in a large proportion of cases, many able roentgenologists maintain that roentgenoscopy will reveal early gastric cancer with a high degree of accuracy, that inspection of the internal relief is highly informative and frequently indispensable, and that the meniscus complex, properly determined, is consistently indicative of ulcerating carcinoma. Apparently the authors are not familiar with, or they do not endorse, the quick staining method of frozen sections, which was developed in this country. Their attitude on gastritis as a precursor to cancer, and on gastroscopic diagnosis, will undoubtedly be challenged in many quarters. Only a few of the important American contributions to the subject of gastric cancer masquerading as benign gastric ulcer are cited.

Traité d'ophtalmologie. Publié sous les auspices de la Société française d'ophtalmologie. Par MM. P. Baillart, Ch. Coutela, E. Redslob, E. Yelter. René Onfray: Secrétaire général. Tome IV: Pathologie (suite). Par MM. A. Cuénod et al. Cloth. Price, 400 francs. Pp. 890, with illustrations. Paris: Masson & Cie, 1939.

The fourth volume of this new French encyclopedia follows the general form of its predecessors and is given over to the pathologic conditions of the anterior portions of the eye. The text consists of the pathology of the lacrimal apparatus by Vallière-Vialeix of Limoges, diseases of the conjunctiva by Renard of Paris and Nataf of Tunis, trachoma by Cuénod and Nataf of Tunis, conjunctival lesions resulting from systemic disorders and exanthems by Genet of Lyons, conjunctival lesions produced by chemical substances or by products of animal or vegetable origin by Genet, conjunctival lesions produced by physical agents by Genet, new formations and tumors of the conjunctiva by Merigot de Trigny of Paris, diseases of the cornea by Prêlat of Paris, diverse disorders of the cornea by Kleefeld of Brussels, and diseases of the sclera by Petit of Paris. Naturally with such a variety of authors there is a wide variation in the character of the individual chapters. The first 300 pages of the book is devoted to diseases of the entire lacrimal apparatus and nowhere in the literature is there such a careful systematic compilation as this. That chapter is profusely illustrated by reproductions of photographs, mostly black and white. The pictures of the external face are good, the reproductions of roentgenograms of the tear passages are rather indifferent, and the photomicrographs of the pathologic changes are excellent. The remainder of the book is extensively illustrated with color plates, some reproductions of drawings and some color photographs. On the whole these are excellent, particularly those showing biomicroscopic aspects. Unfortunately, the chapter dealing with the cornea contains comparatively few and rather indifferent illustrations. Particularly appropriate at this time is an eight page section that starts with the following short paragraph: "The appearance of the ocular manifestations due to yperite date from the end of July 1917. At that period the British front in the Ypres-

sector was subjected to a bombardment by poisonous substances which were up to that time unknown and which produced the ocular disturbances that we are about to describe. Hence the name 'yperite.'" Then follows a careful description of the inflammation of the eyes caused by yperite, or mustard gas, together with treatment and prognosis. To the American ophthalmologists who were not at the front, this condition is practically unknown. By and large, volume iv is up to the standard set for the entire encyclopedia. In some ways, particularly color reproductions, it surpasses its predecessors, while in some chapters the text matter is not as complete as could be wished for in a work of this extent. However, it is so good that it is to be devoutly hoped that the war will not interfere with the completion of the series.

Medical Climatology: Climatic and Weather Influences in Health and Disease. By Clarence A. Mills, Ph.D., M.D., Professor of Experimental Medicine, University of Cincinnati, Cincinnati. Cloth. Price, \$4.50. Pp. 296, with 90 illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1939.

Chapter I opens by differentiating sharply between weather and climate. By weather in a meteorologic sense is meant the sum total of atmospheric conditions prevailing from hour to hour and from day to day or week to week. Climate, however, refers to average conditions over many years or decades and while more stable than weather should not be thought of as a fixed term to cover unchanging values. This book deals definitely with variations in climate; i. e., different climatic areas rather than with weather as defined. Climate, Mills says, plays a distinct part in average body heat loss and energy output, therefore exerting a preponderant role in the existence of man and other warm blooded animals. There is a climatic dominance of growth, fertility, metabolism, body resistance, vascular system and other human functions. Mills has not attempted in this book to cite the mass of evidence for the role of climate in so many functions and human diseases. In spite of the author's statement in the preface that he does not desire to hold climate and weather responsible for all human reactions, the reading of the book demands the constant exercise of the critical faculties to avoid this conclusion. Pitfalls are numerous and many readers will have difficulty in grasping such statements as this made on page 184: "World leaders listed in Who's Who and other similar volumes, and the presidents of the United States, have largely been born in the more stimulating and unstable first half of each year. The feeble-minded, on the other hand, are more often conceived in summer or early fall, when fewer superior minded individuals are being conceived. And in the matter of admission to mental hospitals, this same relationship to seasonal stress is found." Many statements perhaps equally difficult to confirm are made in other portions of the book but may not be quite so obvious.

Opuscula selecta Neerlandicorum de arte medica. Fasciculus quintus-declmus quem curatores miscellaneorum quae vocantur Nederlandsch Tijdschrift voor Geneeskunde collegerunt et ediderunt Amstelodami Sumptibus Societatis. Petri Camperi itinera in Angliam 1748-1785. [Selected Dutch Writings on Medical Art. No. 15. Travels of Petrus Camper in England 1748-1785.] Cloth. Pp. 264, with illustrations. Amsterdam, [n. d.].

This volume of the remarkable series issued by the *Nederlandsch tijdschrift voor geneeskunde* contains the diaries of Petrus Camper, "the most famous Dutch doctor of the second half of the eighteenth century," during his visits to England in 1748-1749, 1752 and again in 1785. B. W. T. Nuyens writes an interesting introduction and critical review of the diaries. The diaries are in the Dutch language, with translation into English on the opposite pages. The diary of the first visit to London is accompanied by "annotations to a course of lectures on midwifery delivered by the wellknown Doctor W. Smellie" in Latin with English translation and illustrated by facsimile reproductions of the title page of the summary of Smellie's course and of the first two pages of Camper's annotations. The diaries record in detail Camper's daily experiences during his English visits. "When in 1748 as a young doctor, in 1752 as a youthful professor at Franeker's university, he [Camper] went to England he did this to improve his skill in the medical science, preferably in midwifery. When, thirty-seven years later, in 1785 he revisited England, he went as a scientific man of mature experience, to communicate to his English colleagues his

self-assured ideas on obstetrics, the fruits of . . . a long practice." During his second visit William Hunter invited him to dinner, of which he writes: "Had dinner at Hunter's on Wednesday (19th July) and saw his drawings of the uterus gravidus, which were very finely drawn by Rymsdyk." There are seventeen illustrations which show portraits of Camper, several drawings by him, and also a portrait of Smellie by himself. At the end are biographic notes of persons mentioned in the diaries. Readers of medical history, and especially those concerned with obstetric history, will find this book of exceptional interest.

Traffic in Opium and Other Dangerous Drugs for the Year Ended December 31, 1938. Report by the Government of the United States of America. U. S. Treasury Department, Bureau of Narcotics. Cloth. Price, 20 cents. Pp. 122, with illustrations. Washington, D. C.: Supt. of Doc., Government Printing Office, 1939.

This report by the Commissioner of Narcotics to the Secretary of the Treasury deals with the calendar year ended Dec. 31, 1938. It indicates that there are still seven states which have not passed the uniform narcotic drug act; namely, Kansas, Maine, Massachusetts, New Hampshire, Washington, North Dakota and Vermont. The control of drug addiction in the United States continues to be satisfactory. Apparently the number of drug addicts has decreased from ten per 10,000 persons in 1924 to two per 10,000 persons at the present time. The treatment used in the government hospitals includes withdrawal of the drugs within fourteen days, warm baths, sedatives when necessary, and supplementary measures as indicated. A recent survey indicates that three years after the date of discharge 34 per cent have not relapsed. Research is being conducted as to non-habit forming drugs which may be used to replace opium. Studies are also being made on narcotic addiction and crime. In the section of the book devoted to traffic in opium there are some interesting stories dealing with illicit traffic in narcotic drugs, each of them dramatic and each of them indicating the difficulty in controlling illicit traffic in opium. The records fortunately report but few instances in which physicians have been conspicuously mixed with this traffic. The per capita consumption of opium in the form of all its salts, derivatives and preparations amounted to approximately 7.4 grains for 1938. The per capita consumption of cocaine alkaloid was approximately 0.09 grain.

The History of the Forceps: An Investigation on the Occurrence, Evolution and Use of the Forceps from Prehistoric Times to the Present Day. By Vilhelm Mjller-Christensen. (With a Summary in Danish). Denne Afhandling er af det lægervidenskabelige Fakultet antaget for den medicinske Doktorgrad, København. Translated from the Danish by W. E. Calvert. Paper. Pp. 298, with 441 illustrations. Copenhagen: Levin & Munksgaard; London: Oxford University Press, 1938.

In 1931 the author devised a three legged suture forceps and before publishing a description of it he reviewed various German, British and French instrument catalogues to make certain that his invention was original. He was amazed to find that in one catalogue (Jetter and Scherer's Aesculap Musterbuch) there were more than a thousand different forceps. Of course, many of the models differed only slightly but there were at least 200 different types. The author then undertook to study the sources from which this "world of forceps" arose. For this purpose he reviewed not only medico-historical but also archeological literature. Furthermore, he visited many museums both in his native country (Denmark) and abroad (Sweden, France, Italy, Great Britain and Germany). Illustrations were made of a large number of different types of forceps and in this book the author has included 441 of them. The author defines forceps as a gripping instrument which consists of two legs joined together in a hoop, or forged solidly together or emanating from a solid metal rod and terminating at the other end in the gripping parts, the jaws. The author points out that the original model of the forceps was the hand, when its thumb and index finger are used for gripping. When the hand, used as a forceps, grips coarse objects the finger pulpa act as the jaws, whereas when gripping finer objects it is the nails that act as the forceps jaws. The book is extremely interesting and abundantly illustrated. It represents an enormous amount of hard work and considerable travel, and the author is to be congratulated on his accomplishment.

Diseases of the Mouth and Their Treatment: A Text-Book for Practitioners and Students of Medicine and Dentistry. By Hermann Fridz, A.M., D.D.S., M.D., and Sigmund S. Greenbaum, B.S., M.D., F.A.C.P., Professor of Clinical Dermatology and Syphilology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price, \$9. Pp. 670, with 336 illustrations. Philadelphia: Lea & Febiger, 1939.

This is a collection and evaluation of important contributions concerning the diseases of the mouth and their treatment, the second edition of a work designed as a textbook for students and practitioners of medicine and dentistry. In this edition the book has been thoroughly revised and a new chapter on lymphadenitis has been added together with articles on Paget's disease (ostitis deformans), Schüller-Christian disease, hereditary pseudohemophilia, sarcoidosis and many other conditions productive of mouth lesions. In addition there are articles on microscopic technic, roentgenographic examination, mouth breathing, harelip and cleft palate, and diseases of the mouth associated with nervous disorders. There is also a complete classification of tumors of the mouth. Seventy-five illustrations have been added and many of the older ones have been replaced. Since this book is intended as a textbook rather than a reference work, some of the subjects of lesser importance are given only a little space. Those of importance are handled adequately. Nothing of importance has been omitted, and though the book is of only medium size it is an adequate discussion of the common diseases of the mouth and of every disease productive of mouth lesions. The text is well written, the illustrations are for the most part excellent. The type is large and legible. It should satisfy a need long felt by dermatologists, oral surgeons and the general practitioner.

Die Pflege des gesunden und kranken Kindes: Zugleich ein Lehrbuch der Ausbildung zur Säuglingspflegerin und Kinderkrankenschwester. Unter Mitarbeit von R. Bittner et al. Herausgegeben von Prof. Dr. med. Werner Cattel, Direktor der Universitäts-Kinderklinik und -Poliklinik, Leipzig. Paper. Price, 18 marks. Pp. 764, with 423 illustrations. Leipzig: Georg Thieme, 1939.

This is the longest textbook for nurses and nursemaids that has ever been written. One wonders whether a volume of 764, large pages will ever be read by nurses or nursemaids. The section on anatomy and physiology is excellent and would do justice to a special treatise on the anatomy and physiology of childhood. The rest of the book is well written but not as well as the first section. The book is all inclusive. It not only covers the ordinary care of the healthy and the sick child but it includes also a section on public health, child education and psychology, child play, and a section on the health of the mother. Significant of the present day political trend is the inclusion of a section on race theory. The content in this section, however, is mainly biologic. Significant also is an illustration in the chapter on play showing miniature soldiers and cannons as toys for children. The illustrations in the section on anatomy are excellent. Most of the illustrations in the other chapters are too small and some of them are indistinct.

Pathologie chirurgicale de la rate. Par Pierre Golnard, chirurgien des hôpitaux d'Alger. Paper. Price, 55 francs. Pp. 174, with 15 illustrations. Paris: Masson & Cie, 1939.

This monograph is the sixth in a series concerned with various diagnostic procedures and pathologic conditions of the spleen. The present volume, although dedicated to the surgical pathology of the spleen, covers a much wider field and considers in some detail almost all the important disease conditions which may affect that organ. The author particularly emphasizes the necessity for the clinician and surgeon to cooperate closely before surgical intervention is recommended. Ptosis of the spleen and torsion of the splenic pedicle, contusions and ruptures, as well as wounds and herniation of the spleen, are carefully considered and in most cases splenectomy rather than some other conservative operation is indicated. Splenomegaly due to various types of infections receives detailed mention, the chapter on hydatid cysts of the spleen being particularly valuable. The last half of the monograph is devoted to a consideration of the splenomegalies associated with pathologic blood conditions, changes in the liver and gastrointestinal hemorrhages, with a further chapter on Gaucher's and the Pick-Niemann disease. The author concludes that splenectomies are particularly valuable in hemolytic icterus and

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Life Insurance: "Sound Health" and "Serious Disease or Complaint" Construed.—The defendant insurance company issued two life insurance policies which provided "If, . . . the insured . . . is not in sound health on the date hereof . . . or has, within two years before the date hereof, been attended by a physician for any serious disease or complaint . . . the Company may declare this policy void." On the death of the insured the defendant insurance company refused to pay the benefits stated in the policies, alleging that within the two years preceding the issuance of the policies the insured had been attended by a physician for high blood pressure, which the company claimed was a "serious disease or complaint." The plaintiff, the administratrix of the insured's estate, then brought suit. The trial court rendered judgment in favor of the plaintiff, but on appeal to the supreme court of New York, appellate division, fourth department, 252 App. Div. 926, 300 N. Y. S. 182, this judgment was reversed and the complaint dismissed. From the latter judgment the plaintiff appealed to the Court of Appeals of New York.

The evidence showed that the insured had suffered from high blood pressure, accompanied by dizzy spells, prior to her application for insurance, but there was also evidence that the insurer's agent knew of the insured's condition. A physician who attended her four months prior to the issuance of the policies testified that at intermittent periods she had a systolic blood pressure of between 190 and 200, but he did not testify either that she was suffering from a serious disease or complaint or that she was not in sound health. The evidence showed, too, that the insured, when she applied for insurance, was able to do her own housework and that the insurer's physician who examined her before the policies were issued reported that she was in good health.

Evidence could not properly be admitted, said the Court of Appeals, to show that the insured falsely stated in her application that she had not been under the care of a physician for three years, although in fact she had been attended by a physician within two years. Section 58 of the Insurance Law of New York requires that an insurance policy contain the entire contract and provides that nothing can be incorporated therein by reference. Consequently false statements, oral or written, made to induce an insurance company to issue a policy of insurance, even though they are material, do not constitute a defense unless they are attached to or endorsed on the policy. In the present case, the applications for insurance were neither attached to nor endorsed on those policies and so the statements in the applications were not warranties.

The burden of proof, said the Court of Appeals, rested on the insurer to justify its voiding its policies. It had to establish either that the insured had been attended by a physician for a serious disease or complaint within two years of the issuance of the policies or that she was not in sound health at the time the policies were issued. What constitutes a serious disease or sound health is ordinarily a matter of opinion. A condition which in one person might constitute a serious disease or complaint in another person might not be considered serious. The defendant, in the opinion of the court, failed to establish as a matter of law that the insured was not in sound health at the time the policies were issued or that she was suffering from a "serious disease or complaint."

There was evidence from which, the court thought, the jury could have found that the insurer's agent knew of the condition of the health of the insured. The court, however, was not in sympathy with the insurer's contention that because the agent had no authority to change the conditions of the policies the doctrine of equitable estoppel should not apply against it. Knowledge of the agent constituted knowledge on the part of the insurer. It would be a fraud on the policyholder to permit an insurer to accept premiums on a policy which it knew was void from its inception. Neither did the court look with favor

on the insurer's contention that because the insured had not disclosed to the insurer's medical examiner the information that she had previously given to the insurer's agent, the insured should not be estopped. The insured might well have believed that the medical examination had been required because of the information which she had given to the agent. Moreover, if the jury found, as apparently it did, that the insurer had not proved that the insured was not in sound health or had been attended by a physician within two years before the issuance of the policies for any "serious disease or complaint," the question of waiver or estoppel would be unimportant, and the trial court correctly so instructed.

The Court of Appeals ordered the judgment of the supreme court, appellate division, reversed and the judgment of the trial court in favor of the plaintiff affirmed.—*Lampke v. Metropolitan Life Ins. Co. (N. Y.), 18 N. E. (2d) 14.*

Basic Science Acts: Application for Exemption Tardily Filed.—The basic science act of Oklahoma, which became effective April 19, 1937, exempted from its requirements "Indian Herb Doctors, Herb Doctors or Doctors who administer simple remedies who register with this board [the basic science board] within sixty (60) days after the passage of this Act and who have practiced in Oklahoma for two (2) years." On June 18, 1937, the last day on which registration under the foregoing provision could be made, the defendant Adamson deposited in the United States mail at Oklahoma City an application, addressed to the secretary of the basic science examining board of Oklahoma, for exemption as a doctor who administered simple remedies. This letter was delivered June 21, 1937, or sixty-three days after the basic science act became effective. The board denied the application and Adamson instituted mandamus proceedings to compel the board to register him. The trial court granted the writ of mandamus on the theory, apparently, that the act of mailing the application was synonymous with the act of registering as required by the basic science act. The board thereupon appealed to the Supreme Court of Oklahoma.

In reversing the judgment of the trial court and remanding the cause, the Supreme Court said that where a person is required to register with a certain board within sixty days of a certain date in order to acquire a privilege under the law and he deposits his application in the United States mail on the sixtieth day, addressed to the secretary of the board more than 100 miles away, such act of mailing is not equivalent to registering, and if the application so mailed is not delivered until the sixty-third day it is too late. When a person elects to mail an application for registration, he thereby selects the United States mail as his agency, and the risk of delay in delivering is on him. The general rule, the court pointed out, is thus stated in 46 C. J. 559, sec. 69:

In the absence of custom, statute, estoppel, or express contract stipulation, when a notice, affecting a right is sought to be served by mail, the service is not affected until the notice comes into the hands of the one to be served.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Tract. S. Morrison and M. Feldman, Baltimore.—p. 549.

Carrier State in Amebiasis.—Howard discusses the clinical

state of twenty-two carriers of *Endamoeba histolytica*. These

patients had abdominal complaints other than frank diarrhea or

dysentery; they had no other intra-abdominal or extra-abdominal

disorder. The symptoms in all were severe enough to make

the patients consult their physicians or to make them go to a

hospital dispensary. They were given routine gastrointestinal

examinations, a complete physical examination, blood count,

serologic test for syphilis, gastric analysis after an Ewald test

meal, fluoroscopic examination after the administration of barium

sulfate and proctoscopic examinations and stool studies. The

preliminary diagnoses varied. The most common symptoms

were pain, nervousness, gas with the passage of flatus, mucus

in the stool, alternating constipation and diarrhea, and, uncommon

stools or slight diarrhea. Each of the patients was given ame-

bicidal therapy (emetin, carbarsone and/or chiniofon). Two

and normal 1 to 1 responses was established. The results demon-

strated that digitalis in doses sufficient to induce therapeutic

effects may be given in cases of partial heart block without

causing interference with the orderly passage of impulses from

the auricles to the ventricles. While digitalis and organic heart

disease interfere with auriculoventricular conduction, these fac-

tors do not interfere each other and their simultaneous presence

does not lead to an additive effect when such doses as used in

the present study are utilized. Although digitalis in doses of

from 0.1 to 0.23 Gm. to 10 pounds (4.5 Kg.) of body weight

did not greatly increase preexisting heart block in any case of

this series, it is impossible to preclude the possibility that occa-

sional or rare instances may be encountered in which this may

occur, particularly if dosages approaching toxic amounts are

employed. Therefore the authors warn that caution and careful

observation should be exercised, particularly if larger doses than

those employed by them are utilized.

Pregnancy and Diabetes.—From a study of the records of

353 pregnancies in 242 diabetic women cared for since 1898,

White and her associates find that, excluding surgically inter-

Digitalis and Partial Heart Block.—Because of conflict-

ing opinions as to whether digitalis should be given to patients

with partial heart block, Blumgart and Altschuler observed its

effect on nineteen patients from 15 to 72 years of age with

congestive heart failure. Digitalis was administered in doses

calculated on the basis of body weight, somewhat less than the

full Egleston dosage was administered. Digitalization was

accomplished within three to nine days. Nausea was induced in

six cases and in these no significant change in PR interval

occurred. In two of these cases, changing 2 to 1 and 1 to 1

responses were present before and after digitalization. Of the

nineteen cases studied, the PR interval did not change in eleven,

in three a lengthening of 0.02 second and in three a lengthening

of 0.04 second occurred, in one the PR interval was shortened

by 0.04 second and in another the PR interval was shortened

by 0.08 second. No alteration in the orderly sequence of auricu-

lar and ventricular contractions occurred except that observed

in one case in which occasional 2 to 1 heart block disappeared

and normal 1 to 1 responses was established. The results demon-

strated that digitalis in doses sufficient to induce therapeutic

effects may be given in cases of partial heart block without

causing interference with the orderly passage of impulses from

the auricles to the ventricles. While digitalis and organic heart

disease interfere with auriculoventricular conduction, these fac-

tors do not interfere each other and their simultaneous presence

does not lead to an additive effect when such doses as used in

the present study are utilized. Although digitalis in doses of

from 0.1 to 0.23 Gm. to 10 pounds (4.5 Kg.) of body weight

did not greatly increase preexisting heart block in any case of

this series, it is impossible to preclude the possibility that occa-

sional or rare instances may be encountered in which this may

occur, particularly if dosages approaching toxic amounts are

employed. Therefore the authors warn that caution and careful

observation should be exercised, particularly if larger doses than

rupted pregnancies, the fetal mortality in the preinsulin era was 44 per cent and in the insulin era 38 per cent. In the preinsulin era, early and late fetal deaths occurred with equal frequency. In the insulin era, 60 per cent of the fetal deaths were late because of stillbirth or neonatal accidents and 40 per cent because of spontaneous abortions. The authors believe that severe diabetic crises—coma and hypoglycemia—are not at all incompatible with the birth of a living child. Thus among fourteen accidents in late pregnancy maternal coma occurred only twice, in each instance precipitated by infection, and the remaining twelve patients had no signs of acidosis. The latter had taken meticulous care of their diabetes to ensure the birth of a living child. In contrast to this experience, other patients careless of the diabetic routine have had a successful outcome of the pregnancy. It became evident to the authors that stillbirth was not related to diabetes or its specific complication (coma) but was definitely related to preeclamptic toxemia and as time elapsed that the accidents—neonatal death and premature delivery—were also related to the abnormal hormone picture. The relationship of toxemia and stillbirth first became apparent to them when they observed that in many diabetic women the course of pregnancy was uneventful until the sixth month, when at any time thereafter edema, albuminuria and a rising blood pressure developed in the patient. Shortly after the rise of the blood pressure the fetus died and the signs of toxemia promptly disappeared. The entire clinical picture can occur and disappear in as short a time as one week, but it is predicted from four to six weeks by the rise of gonadotropic substance in the serum. Of thirty-five completed pregnancies studied for determinations of gonadotropic substance in the serum, nine were of former juveniles—patients with onset of diabetes before 15 years of age. In only one case did the onset of diabetes occur during pregnancy, and insulin was required in only one. Diabetes was severe or moderately severe in twenty-six. Coma developed in one case and hypoglycemia for three days in one, following the mistaken administration of 276 units of protamine zinc insulin. In general, the control of diabetes was good in all cases. The clinical course in the fourteen cases in which the values for serum gonadotropic substance were repeatedly normal was completely uneventful. Complications developed in the ten cases in which the values for serum gonadotropic substance were supernormal and no treatment was given. Toxemia developed in seven. Premature delivery occurred in the remaining three. In two successive pregnancies in the same case in which values for gonadotropic substance were supernormal but steadily fell the fall was preceded by a rise of estrogen four weeks prior to the normally expected time. During the first pregnancy well marked signs of toxemia developed. These decreased in severity with the fall of gonadotropic substance. Less well defined signs in the second pregnancy disappeared entirely. The biochemical behavior in this case gave further presumptive evidence of the probable value of estrogen therapy. Massive doses of estrogen were administered in nine cases in which the values for serum gonadotropic substance were supernormal, from 150,000 to 300,000 international units as progynon B being given and in addition progestin. Replacement treatment was followed by a drop in serum gonadotropic substance controlled by the size and frequency of the dose of estrogen. No instance of progressive toxemia occurred. Not one woman miscarried. There was a tendency for the serum protein which fell to low levels to rise without change in diet, the weight to fall, the urinary output to be increased, the albumin to be diminished and the blood pressure to fall. Therefore it seems that the test for gonadotropic substance permits one to classify the cases according to hazard and to gauge the effect of therapy.

Erythropoiesis Following Bleeding Peptic Ulcer.—Lyons and Brenner evaluate, in 237 admissions of bleeding peptic ulcer, the problems presented by the anemia that follows hemorrhage. Special attention has been given to the symptoms resulting from the hemorrhage and the rate of recovery of the erythrocytes after the hemorrhagic episode. In all these cases there was either x-ray or postmortem evidence of peptic ulcer or a clinical diagnosis of a peptic ulcer based on typical symptoms

of long duration or a definite history of melena or hematemesis either within a month before entry or during hospitalization. The authors found that the greater the anemia the greater was the average daily increment of erythrocytes. From average weekly erythrocyte counts it is seen that the erythropoietic response of the body is determined by the degree of the anemia at the moment and is independent of the initial severity of the hemorrhage itself. The observed erythropoietic rate for cases in this series, in the large majority of which a Sippy regimen was prescribed, was fully as good as that reported for cases in which a liberal "puréed diet" and iron were employed. Beyond the actual increment of donated cells, transfusion appears to have no effect on the rate of erythropoiesis. The net mortality for the series was 5.5 per cent. This appeared to be independent of sex or number of previous hemorrhages.

Cystine Hydrochloride as Anticoagulant.—Putnam and Hoefler state that the intracardial injection of cystine hydrochloride into dogs was followed by a rise in coagulation time of from 40 to 100 per cent in three of five experiments. The administration of cystine hydrochloride to dogs by stomach tube was followed by an increase of clotting time of from 25 to 100 per cent in all technically satisfactory experiments. Cystine hydrochloride also was administered by mouth in twenty-three cases in which the diagnosis of multiple sclerosis had been made. In seventeen a rise of coagulation time was observed, which varied from 30 to 90 per cent. Cystine hydrochloride is well tolerated by most patients in daily doses up to 3 Gm., over many months. No serious symptoms have been observed to follow its use. It is therefore suggested as an anticoagulant of rather low efficiency for use over long periods for conditions in which such an agent might be valuable.

Sulfanilamide Irrigations for Gonorrheal Conjunctivitis.—Rein and Tibbetts compare the results of fifteen cases of gonorrheal ophthalmia treated by earlier methods with those of fifteen cases treated with sulfanilamide irrigations. A special nurse irrigated the infected eye or eyes every fifteen minutes, night and day, with a 0.5 per cent solution of sulfanilamide made up in physiologic solution of sodium chloride. The amount of solution used in the irrigations varied, but an amount sufficient to keep the eyes clean was administered consistently. In cases in which other gonorrheal complications were present—vaginitis or urethritis—supplementary sulfanilamide, from 30 to 60 grains (2 to 4 Gm.), was usually given orally, according to the age and weight of the patient. At the end of twenty-four hours the cornea was usually cleaner and brighter, secretion of pus was almost stopped, edema of the lids was rapidly receding and when the complication of corneal ulcer was present the lesion advanced no further or began to heal. Smears were taken daily from the conjunctival sac, and the patient was discharged when three consecutive daily smears showed that intracellular or extracellular diplococci were absent. To date there have been no relapses. In the first fifteen cases the average number of days before a negative smear was obtained was 27.2, while in the fifteen treated with sulfanilamide it was 6.8 days. The sulfanilamide treatment was not abetted by additional therapy; the patients were given only adequate balanced meals and general care, together with attention to any coincidental complications. The economic advantages resulting from the reduced period of hospitalization compared to that required by other standard measures are obvious.

Paraplegia After Use of Frei Antigen.—Keim and Wakefield cite a case of flaccid paralysis which began eleven days after the intradermal diagnostic use of commercial mouse brain Frei antigen. Almost complete recovery had taken place four months later. The causative mechanism of these accidents is unknown. The authors feel that the cause must be sought not in the substances administered but in a constitutional predisposition of the person affected. The recent work on virus proteins and inapparent viruses suggests that altered virus activity might help clarify the nature of this individual susceptibility. The theoretical explanation offered is that after a period of incubation following nonspecific trauma of the skin (such as vaccination, injection, exanthems or virus eruptions) the patient responds with an interruption of his immunity by a reactivation of inapparent or latent viruses. This state of altered activity then leads to the production of paralysis and other unexplained clinical accidents.

Syphilis and Tuberculosis in the Negro.—As the literature concerning dual infection with syphilis and tuberculosis contains extremely divergent opinions, Goldblatt reviewed the records of 25,472 ambulatory Negro patients of all ages in an attempt to solve some of these difficulties. The diagnosis of syphilis was based on complete physical and routine serologic investigation of all applicants (by Wassermann, Kahn or Kline tests and usually by all three). Darkfield studies of doubtful open lesions and examinations of the spinal fluid of patients with suspected syphilis were carried out whenever possible. Serologic tests, including provocative procedures, were repeated whenever there was any reason to suspect the presence of syphilis. The diagnosis of tuberculosis was based on physical examinations together with fluoroscopic and x-ray studies of the chest. Investigation of the sputum for tubercle bacilli and guinea pig inoculations were made when the fluoroscopic and x-ray results did not confirm the physical observations. Necropsies were performed on 41 per cent of the patients who died (315), and the diagnosis of tuberculosis was confirmed in all cases in which section was done. Of the cases in which tuberculosis and syphilis were concomitant (186), anatomic evidence of syphilis was found in 34 per cent. It is probable that the distribution brought out by the investigation is representative of the Negro population of Cincinnati, as about half of the entire Negro population of the city came under observation. It was found that 33.7 per cent of the entrants to the clinic had syphilis either alone or combined with tuberculosis, whereas only 4.9 per cent came in with this specific complaint. Of the 2.5 per cent of patients diagnosed as having tuberculosis only 1.2 per cent were aware of their condition on entry. Tuberculosis was found in 318 (2 per cent) of the 16,919 patients without syphilis and in 326 (3.6 per cent) of the 8,556 patients with syphilis. Almost double (1.8 times) the amount of tuberculosis was found among the syphilitic as among the nonsyphilitic patients. Tuberculosis alone was more frequent in the younger patients than was syphilis alone. On the other hand, tuberculosis combined with syphilis (326 instances) was relatively more prevalent in the older age groups. Therefore the 310 patients who had contracted syphilis first must have contracted the tuberculosis at higher ages. It is shown that patients with syphilis are susceptible to tuberculosis at the higher ages to a much greater degree than are those who are free from the ravages of syphilis. Among nonsyphilitic persons tuberculosis enters at a maximal rate in the twenties, falling away at lower and at higher ages.

Among syphilitic persons the incidence of contracting tuberculosis increases steadily with age to about the age of 40 and then appears to level off or to decrease somewhat. Mortality rates for tuberculosis were increased by the presence of associated syphilis, particularly when the latter was in a late active stage. Antisyphilitic treatment administered to patients with both tuberculosis and syphilis prolonged life. It appears that the control of syphilis among Negroes will assist substantially in the control of tuberculosis.

Boxer's Hemorrhage.—Carr and Moody add three cases of hemorrhage to a case encountered by Moody in 1931 in which a boxer died after a severe beating. At necropsy scattered small contusion-like hemorrhages in the cortex, cerebellum and stem were found. The three present cases of contusion hemorrhages of the brain occurred in the stem after fisticuffs which produced no fracture of the skull or injury elsewhere in the brain, either cerebral or cerebellar. With the person, at least in the terminal stages of the beating, only partially conscious or, in the boxing terminology, "out on his feet," the musculature is more relaxed than normal, and muscle tone is definitely decreased. The motion of the head on the cervical vertebrae is more pronounced than during the usual state, and more acute angulation of the brain stem is possible on flexion and extension of the head. Because in the three cases that the authors encountered hemorrhage occurred in connection with fisticuffs of some nature, the specific and limited injury is regarded as peculiar to boxers or fighters—to those who are involuntarily beaten or in whom the type of injury causes acute angulation and pinching of the pons and medulla over the tentorium. The term "boxer's hemorrhage" is suggested for these injuries.

Cardiac Slowing from Digitalis in Auricular Fibrillation.—Gold and his colleagues studied the mechanism of cardiac slowing due to digitalis in ten patients with auricular fibrillation. Within a certain range of dosage the level of the ventricular rate in a given individual with auricular fibrillation may not reveal which of the two mechanisms (vagal abolished by atropine and extravagal not abolished by atropine) predominates, for the control of the rate may pass from the vagal to the extravagal factor as the dose is increased and in the reverse direction as the drug is eliminated, without a conspicuous change in the ventricular rate. This is due to reflex changes in vagal tone which play an important part in the ventricular slowing by digitalis in auricular fibrillation. An increased vagal tone in one stage of the action of digitalis and a decreased vagal tone after more intensive digitalization are the results of reflex adjustments. Depression of the vagus as a significant factor in the action of digitalis has not been considered heretofore. The results of the study suggest that the dose of digitalis should be reconsidered in the light of whether the vagal or the extravagal control of the ventricular rate is the more favorable mechanism for maintaining the optimal state of persons subject to auricular fibrillation and heart failure.

Paredrine for Fall in Blood Pressure in Spinal Anesthesia.—Altschule and Gilman point out that paredrine (p-hydroxy- α -methyl-phenylethylamine hydrobromide), a drug recently introduced, has a powerful pressor action due to stimulation of the smooth muscle of the arterial wall and is effective when given by mouth, intramuscularly or intravenously. Good pressor effects are obtained with 20 or 30 mg. orally, 10 or 20 mg. intramuscularly and 5 or 10 mg. intravenously. These results suggested that the drug might be useful in correcting the fall in blood pressure observed during spinal anesthesia. The purpose of the present communication is to report the results obtained with paredrine in fifty cases. Measurements of pulse rate and blood pressure were made every five minutes; when the latter fell markedly, paredrine was administered in doses of 10 to 20 mg. intramuscularly or 5 to 10 mg. intravenously, or both. In every case the administration of paredrine was followed by a return of blood pressure to a satisfactory level. The pressure usually began to rise within five minutes after the intramuscular injection of 10 mg. of the drug; if no rise was noted at this time, a second injection of the same dose was given. This invariably secured the desired result. The authors conclude that paredrine is useful in raising the blood pressure to satisfactory levels if it becomes unduly lowered by spinal anesthesia. The pulse rate is maintained at, or returns to, levels obtaining before the induction of spinal anesthesia. Paredrine has little or no direct effect on the heart, its direct action being apparently limited to the peripheral vessels. No untoward effects have been noted after its administration.

Depression as Chief Symptom.—Ziegler studied 111 patients whose first chief symptom consisted of well defined attacks of depression or low spiritedness. Their ages ranged between 16 and 77 years. Sixty-five were men. Essentially all occupations and the major professions were represented among them. Possessed of serious and sensitive natures, with a rigid singleness of purpose in their drives to succeed, they were not interested in hobbies and avocations. The majority leaned to the side of being introverted, self-centered persons. The onset of their depression was usually insidious and coincident with family trouble, financial loss, sickness or death. While depression was obvious enough when the patient consulted the surgeon or internist, it was not the earliest manifestation of the disorder for which relief was being sought.

This often proved to be a slowing up, a withdrawal from the usual activities, fatigue, loss of appetite and weight, and insomnia. Depression, worrisomeness, anxious concern about self, shame at the disorder, sadness, melancholy, despondency and low spirits usually appeared later to their fullest extent. Unusual and oftentimes mystifying bodily sensations were common, leading many of the patients from physician to physician and some finally to various creeds, cults and quacks. First-hand data about thought and activity were ascertained only by friendly conversations and visits. Appraisals of thought, emotional state and activity are no less significant than ascites, heart murmurs or other signs of disease. These patients talked about themselves—out of all proportion to everything else. Not only was thinking slow, labored and limited in scope, but most of it was devoted to disagreeable topics which would correlate all too poorly with the actual events of life. Many patients traced the onset of the illness to the late winter or early spring months. The parents of many were of diverse temperament or personality makeup. The study of the previous lives of these patients shows the methods employed to cure the pathologic emotional state. When surgery was resorted to it tended to be directed to the thyroid. Even today goiter is too generally believed to be a cause of depression (often called nervousness). Mucous colitis or allergic phenomena were too readily accepted as causes when in reality they were more likely to be effects of the pathologic emotional state. These patients were grossly and quite universally misunderstood, which added much to their already great discomfort. Some of them were accused by relatives or friends of "putting on" their illnesses "or imagining them" and were upbraided for lack of self control. It is best for the patient of this type to go to a suitable sanatorium or hospital and, as far as possible, to make this step of his own volition. In treating these patients sleep was restored as far as possible by medicines and warm baths were used in moderation and were properly timed. Mild sedatives were given to relieve the daily distress, which is usually at its worst in the morning. The diet was organized so that lost weight tended to be regained. The hands were kept busy so that the patient had less chance to think of morbid things. Reasonable assurances of a favorable outcome were implied. The author has witnessed the recovery of depressed patients 75 years of age. He has also seen patients recover after being depressed for ten years or longer. But exact science has yet to evolve a specific method of cure, despite the startling immediate effects of metrazol and the claims for treatment with estrus-inducing products. From one to two years after treatment fifty-seven patients were heard from or were reexamined. Four had grown worse and two of these were in a state hospital. The condition of sixteen was unchanged. Thirty were improved and one of these was in a sanatorium. Seven were completely well. Forty-two were carrying on at their work as best they could. Since infectious diseases are on the wane, it behooves the next generation of physicians to learn more about the pathologic aspect of depression. The prevention of depressions, the author believes, should have a place in the public health programs of the future.

Diphenyl Hydantoinate for Psychoses with Convulsions.—Black used diphenyl hydantoinate for seventeen patients with psychoses and convulsions who had not reacted well to other forms of chemotherapy. Two patients had complete relief from seizures (a minimum of six months without a seizure) and seven others had a reduction in the number and severity of seizures. The remaining eight either were not influenced by the drug or showed an increase in the number and severity of convulsions. Mental improvement was in direct relationship to the control or reduction in the number of seizures. Treatment of one patient had to be discontinued because of toxic symptoms, and of three patients because of an increase in the number and severity of seizures. Ten are still receiving the drug. Three died. The author believes that the use of the drug should be restricted to patients who do not respond to less toxic forms of treatment.

Maintaining Nutrition of Surgical Patients.—Stengel and Ravdin call attention to some of the dietary deficiencies of surgical patients. They describe the orojejunal method of feeding and discuss its advantages when there is no interference with the protein regenerating mechanism. It has been their experience that the early introduction of the feeding mixture into the distal jejunum results in the earlier return of peristaltic activity after operation. They have been impressed by the smoothness of the convalescence and by the fact that the patients do not request food, even though orojejunal feeding in some instances has been continued for as long as fourteen days after operation and the calorie intake has not been high. During this time, fluid and electrolyte balance, as a rule, can be maintained without resort to intravenous administration. This is of some importance, for phlebitis frequently occurs when prolonged intravenous therapy, especially with dextrose, is maintained. Frequently the injudicious intravenous use of large amounts of sodium chloride postoperatively precipitates edema when this complication would not have developed had nutrition been maintained and if the water and salt intake were not excessive. Too much emphasis has been placed on the fluid and salt requirements of these patients and too little on associated factors which play an important part in keeping fluids in the blood vessels. The method need not always be used, for not all patients have suffered prolonged nutritional deficits. It can be used, however, for every patient subjected to a gastro-enteric anastomosis when suction drainage is to be carried out after operation, for it simplifies the postoperative management since the nutritional requirements of the patient can be fulfilled more adequately.

Acute Perforated Peptic Ulcers.—A review of the diagnosis, treatment and results in 152 cases of acute perforated peptic ulcer treated surgically at the St. Louis City Hospital during a period of six years is presented by Kelly. All the patients were either on relief or unemployed. There were 124,317 general admissions to the hospital during the six years under study, giving an incidence of 0.0012 per cent of perforated peptic ulcers. Most of the perforations occurred in the middle years of life. All patients 70 or more years of age died. The number of cases that occurred during the four seasons was approximately the same, there being only a slight, but insignificant, increase during the spring and fall months. Only seven patients were women, 4.6 per cent. This ratio of men to women compares favorably with many other reports. A history of previous gastric disturbance was given by 128, or 84.2 per cent, of the patients. This fact indicates that previous gastric disturbances are a valuable aid in diagnosis. The duration of symptoms varied from seven days to fifty-five years. Twenty-four patients experienced the pain of perforation as the first symptom of their gastric disturbance. No relationship was

found between the duration of ulcer symptoms before perforation and the mortality rate. When the patient first experienced the pain of perforation, it was described by sixty-two as being in the epigastrium and general abdomen. The next most frequent location of the pain was in the epigastrium alone, fifty-two times. Generalized abdominal pain was described by twenty-three patients. Fifteen patients described their pain as occurring in the middle or lower part of the abdomen or at the upper right quadrant; 113 vomited after the perforation and before operation, while thirty-nine did not vomit. A study of the symptoms of perforated gastric and duodenal ulcers indicates that an anatomic location of the ulcer cannot be made from the history of the perforation. An acute perforation constitutes a surgical emergency and delay in operation increases the mortality rate. The author believes that the simplest and quickest operation should be performed in acute perforations and that the operation of choice is simple purse-string closure; frequently a tab of omentum was sutured over the closure. This procedure is used with the view in mind of preserving the life of the patient and seems to be attended by the least mortality. Only a small percentage of cases necessitated secondary operations, thus justifying the procedure. Of the 140 cases in which operation was performed drainage was instituted in 102 and the mortality rate was practically the same in the two groups. Thirty-nine, or 27.8 per cent, of the 140 patients operated on died. A postmortem examination was made in the twelve cases in which operation was not done. Three of the patients who were not operated on were more than 71 years of age and were in a moribund state on entry. They died soon afterward. Four were in extremely poor physical condition on entry and supportive measures were instituted, but the patients did not rally enough to justify operating. One patient who died shortly after admission did not have a diagnosis until the postmortem examination. Four incorrect diagnoses were made. The average stay in the hospital for the patients who recovered was 25.1 days. Of the postoperative deaths 51 per cent occurred within the first three days. A follow-up was made on fifty-seven of the 101 patients discharged. A patient was considered as having a good result if he was entirely free from pain and was able to work. A few of these patients remained on a diet. If the patient at times had pain which was easily controlled by a diet, the result was considered as fair. If ulcer symptoms were constant the results were considered poor. By these standards, forty-three were considered as having a good result, ten a fair result and four a poor result.

Treatment of Drug Addiction.—Ossenfort states that with the concept that drug addiction is the result of mental illness treatment at the Fort Worth (Texas) Public Health Service Hospital is divided into three main categories: (1) complete admission study of the patient as a whole to establish a base line

in the individual case; (2) prolonged treatment on the basis of the initial observations throughout the remainder of the patient's stay in the hospital, and (3) adjustment of outside conditions in preparation for his eventual return to society. Since so many addicts are recruited from the more or less unstable portion of the population it is not anticipated that results will ever be uniformly successful. The physical condition of patients is always remarkably improved, and their power of resistance to influences that tend to cause a reversion to narcotics is strengthened in a large majority of cases. It is not hoped, however, to erase in all cases fundamental defects to the point at which they may not become manifest again when the afflicted person is subjected to severe environmental stresses. The results seem to justify the conviction that the management of drug addicts as patients who are mentally ill is logical. It is not believed that a long prison sentence is an aid to rehabilitation. The prevention of addiction among the unstable is only a part of a broad program of mental hygiene. Patients suffering from asthma or migraine are especially susceptible to addiction because of the recurrence of attacks. It is doubtful whether such persons should ever be given morphine. Morphine should never be used to tide a patient over the effect of an alcoholic spree. Thousands of persons have been made addicts by just such treatment. In painful conditions calling for an opiate it is best to start with codeine or, if morphine is at first necessary, to change to codeine as soon as possible. New opiates should be used with caution.

Gas Gangrene.—Williams and Hartzell compare the results obtained in seventeen consecutive cases of proved gas gangrene in which roentgen therapy was administered with those of seventeen similar cases in which the treatment was not given. Cases in which there was bacteriologic proof alone without clinical proof were not included. Seven patients entering the Emergency Hospital who from the nature of their injuries might have developed gas gangrene were treated prophylactically and none had gas gangrene. Conclusions are not drawn from this group, but the authors believe that the possibilities of prophylactic treatment in such cases are suggested. In comparing the mortality rates of the two series the authors point out that of twelve traumatic cases in each group there is a difference of 50 per cent. The only fatality among the twelve patients who had roentgen therapy was of a patient practically moribund when the treatment was started. This patient died seven hours after the first treatment. There were also eight patients (four in each group), all of whom died with arteriosclerotic gangrene complicated by gas gangrene. At necropsy two of the untreated showed gas in the tissues but in none of the four that had been irradiated was there such evidence. Of two patients with diabetic gangrene complicated by gas gangrene, one received roentgen therapy and this was the only recovery in the complicated series. Of those irradiated, none died from gas gangrene; two died from pulmonary embolism, one from pneumonia and the other from arteriosclerotic heart disease. No gas gangrene was present at necropsy in these cases. This type of case constitutes a distinct entity and it is felt that these should not be grouped with the traumatic series. The authors believe that a rational

procedure in any given instance of compound fracture as the patient enters the hospital would be as follows: 1. Conservative surgery—adequate débridement should be done. 2. X-ray examination should be made to determine the extent of the injuries and the presence of gas in the tissues. 3. If gas infection is suspected another roentgenogram should be taken within six hours. 4. If there is clinical, bacteriologic or x-ray evidence of gas gangrene, roentgen therapy should be given at once and repeated at least once every twelve hours for three days.

Ovarian Hypofunction Previous to Climacteric.—Hawkinson discusses the results of estrogen therapy in 300 cases of menstrual disorders associated with ovarian underfunction. Patients with an artificial menopause and, when possible, those with the natural menopause were excluded. Also all patients whose symptoms might be accounted for by organic complications were eliminated. The patients' ages ranged from 14 to 35 years, with an average age of 27 years. The average duration of symptoms was fourteen months with the exception of thirty-four patients who complained of symptoms since the menarche. More than one third of the patients had symptoms soon after pregnancy or abortion and more than 12 per cent after salpingectomy or the removal of one ovary. The symptoms, as in the menopausal syndrome, are due primarily to a deficiency of estrogen and, with the exception of the menstrual disturbances and the changes in the vaginal smears, are of a subjective nature. Nervousness was an almost constant complaint but was seldom objective in type. Fatigability and lassitude were almost as prevalent as nervousness. Almost 40 per cent had disturbances of sleep. Excitability and irritability, reflected by exaggerated response to slight emotional shocks, were common. Gastric disturbances, cardiac symptoms and vague and indefinite pains occurred in many cases without demonstrable pathologic changes. The most common cardiac symptoms were palpitation and tachycardia. Flushes and chills were complained of by 18 per cent of the women. Headaches were complained of by 46 per cent of the patients. Of the 265 who had definite menstrual disturbances, 174 suffered from scanty menstruation. Eighty-nine had dysmenorrhea and an almost equal number had irregular menstruation. Menorrhagia, metrorrhagia and secondary amenorrhea were not as common. A number of patients had two or more disorders of menstruation. Many patients stated that there was a difference in the intensity of the symptoms month by month, suggesting the involvement of one ovary. Only standardized estrogenic preparations were used in treatment. The amount of estrogen required to relieve symptoms varied with each patient. Some patients responded to oral therapy alone, while others required as much as 10,000 international units (2,000 rat units) of estrogen in oil by hypodermic injection three times weekly. Initially the oral preparations were usually administered. If there was no response within three to four weeks, larger doses of estrogen in oil were administered intramuscularly. Combined oral and hypodermic therapy was of advantage in the severe cases. After a satisfactory response had been obtained, the dose was gradually reduced, and only when the patient remained free from symptoms was it discontinued. The average patient required treatment for three or four months. However, fifty-seven women required continuous oral treatment to remain symptom free. With the exception of an occasional local reaction at the site of injection, no ill effects were observed. The subjective symptoms responded more favorably than did the associated menstrual disturbances. Data show that 44.3 per cent were relieved of the majority of symptoms, 31 per cent were improved and 24.7 per cent experienced little or no relief. Forty-four patients (74.5 per cent) found that estrogen decreased the severity and frequency of attacks of menstrual migraine. Fourteen (31.8 per cent) obtained complete relief from headaches. Of the seventy-eight women who complained of occipitocervical aching, sixty-one were relieved. Of the fifty-four patients who had a low hemoglobin with or without a corresponding decrease in the number of erythrocytes, twenty-nine (57.4 per cent) showed improvement in the hemoglobin level and number of erythrocytes following the administration of estrogen. The majority had experienced difficulty in maintaining an improved level with liver and iron therapy.

Neutralizing Antibodies of Serums in Poliomyelitis.—

Burnet and Jackson tested the serums of fourteen patients with clinical poliomyelitis and contacts of these patients for neutralizing antibodies. Of the children with the disease, five possessed antibody at the time of the acute illness. The other nine had insufficient antibody for neutralization and eight of these even when convalescent still had insufficient antibodies for neutralization. Of fifteen contacts six possessed antibodies, nine did not. Therefore it is seen that serums show no indication of an increase in serum antibody as a result of (or concomitant with) infection or contact. Some of the children with paralytic poliomyelitis had antibodies at the onset of the disease, while others who had none at the onset still had none some months later. In summary, children in the early stage of acute paralytic poliomyelitis may possess relatively large amounts of circulating antibody or they may have none. In those who have none, none develops within two to three months, in the experience of the authors. It has been assumed that the antibody against poliomyelitis virus which is present in most adult serums results from subclinical infection with the virus at those times when the disease is prevalent in the community. There is fairly substantial evidence that a smaller percentage of adults living in isolated rural communities possess poliomyelitis antibody than is the case in urban populations. The authors state that their results, which are consistent with those of Brodie and others (1937), are completely opposed to such a view unless the unlikely assumption is made that antibody first appears more than a year after the immunizing infection. In monkeys recovering from experimental poliomyelitis antibody appears as a rule from four to eight weeks after infection, and its activity is much lower than that of the average human adult serum. They believe that the best interpretation of the facts is that in human beings the poliomyelitis virus infects only nervous tissues and that in most cases little virus or antigenic material derived from it passes to the antibody-producing cells of the body. Therefore there is no significant appearance of circulating antibody in most instances. Since antibody obviously of specific origin can be obtained in monkey serum after infection, and since certain methods of human vaccination are reported to produce antibody in children, the possibility that a small proportion of individuals do produce antibody after poliomyelitis must be left open, but such production cannot possibly account for the occurrence of relatively high titer antibody in a majority of human beings more than 10 years of age. The orthodox view is that this antibody is a result of a process of widespread latent immunization by subclinical infections with the specific virus. There is no direct evidence in favor of this hypothesis. If specific immunization is excluded there seem to be three possible alternatives for the origin of "poliomyelitis antibody" in human serum: 1. It may develop as a result of a nonimmunologic change in serum globulin, which develops with age in the absence of antigenic stimulus. 2. It may be the response to some commonly encountered antigen which has determinant groups in common with the poliomyelitis virus. The antigen must reach the antibody-producing cells in considerable amount and hence is likely to be derived from a micro-organism which has some invasive power but is not a strictly neurotropic virus. 3. The antibody is a nonspecific or group antibody, appearing as a result of repeated infections with various micro-organisms not necessarily related antigenically to poliomyelitis virus. Of these alternatives it seems to the authors that the second is the most likely and that the antigenic stimulus evidently should be looked for among the micro-organisms (bacteria or viruses) which produce common minor infections.

Antirachitic Value of Human Milk.—According to Drummond and his associates, the mean antirachitic potency of the milk yielded by women on diets supplying in all probability from 100 to 250 international units of vitamin D daily and that of the milk from women given large amounts of vitamin D during the latter half of pregnancy indicates that 10 international units per hundred cubic centimeters of breast milk represents about the normal maximal value. Possibly the same evidence can be put forward to indicate that an intake of about 200 international units represents the minimal daily requirement of the nursing mother. The large doses of vitamin D given to some of the mothers over several months of pregnancy failed to bring about anything approaching a proportional increase in the vitamin D content of the milk. It may be, therefore, that there is an optimal concentration of this substance regulated by the mammary gland. The reason that the assimilation of the bone forming elements is better (from 40 to 60 per cent) when the child is fed on mother's milk than when cow's milk is used (from 20 to 30 per cent) has not yet been determined, but it may be important that the calcium-phosphorus ratio of human milk approximates that of bone mineral, the calcium-phosphorus ratio of cow's milk being considerably smaller. The relatively small concentration of calcium and phosphorus (from 27 to 34 mg. of calcium and from 13 to 17 mg. of phosphorus per hundred cubic centimeters of milk) in human milk as compared with cow's milk (from 100 to 160 mg. of calcium and from 70 to 100 mg. of phosphorus) raises several curious problems, of which the most important has been revealed by the careful studies of Leitch (1937), who has shown that the total intake of calcium when mother's milk is taken, much less the quantity actually retained, is often insufficient to provide the amount calculated as being requisite to maintain the composition of the body either at the maximal figure of 10 Gm. of calcium per kilogram of body weight or at the smaller estimate of 8.13 Gm. This observation led Leitch to consider the possibility that breast-fed infants must often exhibit not only imperfect calcification of new matrix but also osteoporotic changes in bones which at birth were relatively firm. It may be a fact that undetected rachitic changes are much more common in breast-fed infants than is suspected (Maddox, 1932). The authors state that there seem to be only two explanations for Leitch's figures. Either the newborn infant carries a reserve store of calcium sufficient to provide for adequate calcification during the months when the mother's milk does not provide enough or the data of the metabolism experiments which Leitch has used for her analysis are misleading, perhaps because the milk was not of such a quality as to favor optimal calcium retention. It remains uncertain in view of the evidence reviewed by Leitch whether changes in the dietary intake of calcium or phosphorus are reflected to any significant extent in the composition of mother's milk. The authors' results suggest that such an effect is not detectable, at all events in the first two or three months of lactation. Some of the mothers that they observed had been receiving about 2 Gm. of calcium lactate daily during the latter half of pregnancy, but this supplement to calcium-deficient diets did not appreciably influence the calcium content of their milk. There is need for more information not only about the composition but also about the yield of milk from mothers whose diet, adequate in all other respects, provides at least 2 Gm. of calcium, 1.5 Gm. of phosphorus and 300 international units of vitamin D daily. If such milk were made the subject of metabolic investigation on infants it is possible that some of the disturbing discrepancies would be dispelled.

Diabetes and Kidney Failure.—Two cases in which diabetes and nephrosclerosis coexisted are cited by Barlow. The evidence has obvious bearings on insulin therapy. In uncomplicated diabetes, glycosuria may be taken as evidence of a raised blood sugar level which may require to be lowered by

insulin. In the nephritic patient, glycosuria has not the same significance. It is likely to be present in cases in which the blood sugar is not raised to a degree likely to be toxic to cell function, and if insulin were to be pushed in these cases, under the guidance of urinary dextrose, it seems probable that dangerous and even destructive hypoglycemia might be induced. The logical conclusion is that, so far as the diabetes is concerned the patient with mild diabetes is better off with nephritis than without it. Whether this supposition is borne out, time and observation will reveal.

Leukopenic Myelosis.—In this paper Scott uses the term leukopenic myelosis to describe a type of myeloblastic leukemia in which the number of leukocytes in the circulating blood is subnormal for the whole or the greater part of the course of the disease. It is one variety of the complaint to which that contradiction in terms aleukemic leukemia has been applied. It would be idle to suggest that the leukopenia implies a disease process in any fundamental way different from myeloblastic leukosis with a leukemic blood picture, but clinical and hematologic convenience makes a segregation of such cases desirable, for they frequently offer diagnostic difficulty. Leukopenic myelosis is not a rare disease; in the last four years twenty-two cases have been encountered (more than three times the number of analogous leukemic cases seen during the same period) and this paper is concerned with a brief review of the clinical and hematologic observations in this series. A table grouping the patients according to age and sex indicates that no age and neither sex is particularly susceptible. The disease is characterized by three cardinal symptoms: anemia, a hemorrhagic tendency and a liability to necrotic angina. It is possible to differentiate acute, subacute and chronic types. The main characteristic of all forms is a progressive anemia; in acute cases hemorrhagic phenomena and necrotic angina are common. The blood count is characterized by orthochromic or hyperchromic anemia, sometimes with reticulocytosis and erythroblastosis. Leukopenia may persist throughout the course, or a terminal leukemia may occur, especially in the chronic cases. The features of the differential count are the presence of myeloblasts, although the percentage may be below 5 and the hiatus leukopenicus. Thrombocytopenia usually indicates a rapid course. The clinicohematologic picture leukopenic myelosis may be mimicked more or less closely by pernicious anemia, aplastic anemia, granulocytopenia and the leuko-erythroblastic anemias. The sternal puncture, however, determines the diagnosis; it reveals a great preponderance of primitive myeloid cells, most frequently with a predominance of myeloblasts. In two cases evidence was found that the erythropoietic tissues shared in the hyperplasia.

Vitamin B₁ and Cardiovascular Disorders of Pregnancy.—Bickel saw a secundigravida aged 33 in her sixth month of gestation. Anamnesis of her first pregnancy revealed pernicious vomiting, significant loss of weight, palpitation, dyspnea and edemas of the extremities. Similar symptoms characterized also the first half of her second pregnancy with loss of weight from 132, to about 103 pounds (60 to 47 Kg.), pulse 130 beats a minute, the liver overlapping by three fingerbreadths the edge of the ribs, white soft edemas halfway up the thighs, absence of knee jerk and heel reflex, violent pains and formication in the legs. The electrocardiogram disclosed a ventricular complex of low voltage in derivations 1 and 2 and an inverted T wave in derivations 2 and 3. Daily intravenous injections of 50 mg. of vitamin B₁ produced immediate curative effects. Acetonuria and the edemas disappeared after the third day. Restoration of appetite was rapid; the pains in the legs ceased and the electrocardiographic testimony indicated normal conditions. However, vitamin B₁ therapy, reduced to a weekly intravenous injection, was continued until shortly before fetal maturity. At this time the patient weighed 127 pounds (57.6 Kg.) and the x-ray examination of the thorax showed normal heart dimensions. She gave birth to a healthy child. According to the author, cardiovascular disturbances may appear during pregnancy in women who previously were entirely free from them. They are likely to appear in connection with pernicious vomiting or toxicosis of the liver and show a tendency to acidosis and polyneuritic symptoms. Such disturbances may be due, at least in certain cases, to a vitamin B₁ deficiency caused by the intra-uterine needs of the child and the upset of the mother's metabolism. The parenteral administration of vitamin B₁ effective in certain pregnancy polyneuritides is equally effective, the author finds, in certain pregnancy cardiopathies.

Continuous Drip Transfusion.—Grimberg shows that blood transfusion by means of the continuous drip, a method that was first introduced by Marriott and Kekwick, has caused a radical revision in the earlier conception of blood transfusion. Because of the extreme slowness with which the blood is introduced, continuous drip transfusion permits the administration of much larger quantities of blood than did the customary technic. The average duration of the drip transfusion is twenty-nine hours, but it has been continued for as long as sixty hours; the average quantity of blood administered by the continuous drip is 2,700 cc., but as much as more than 6,000 cc. has been given at one time. A quantity of 100 cc. is regarded generally as the best hourly quantity of blood. The author describes the technic of the method and shows diagrams of the apparatus. Evaluating the anticoagulants, he expresses the opinion that heparin is superior to sodium citrate in drip transfusion. He also discusses the indications for this method of blood transfusion, pointing out that Marriott and Kekwick recommended drip transfusion only for the treatment of the various types of anemia, of those due to hemorrhage as well as of those due to toxic, infectious, hemolytic, aplastic and other causes. Other investigators, however, are of the opinion that the method deserves a more extensive application. The author thinks that the chief indication for the drop by drop blood transfusion is to restore in the patient a normal hemoglobin content, whatever may be the initial form of anemia. It is particularly indicated when severe anemia makes doubtful the success of a required operation.

Archivio per le Scienze Mediche, Turin

68: 395-488 (Oct.) 1939

- *Erythroblastic Anemia of Cooley's Type. A. Francaviglia.—p. 395.
- *Anatomy of Erythroblastic Anemia. F. Schiappoli.—p. 457.

Erythroblastic Anemia in Children.—Francaviglia reports five cases of erythroblastic anemia of Cooley's type in children ranging in age from 2 to 8 years. Two of the patients were brother and sister. The disease is of unknown etiology. It is familial and hereditary. As a rule it develops during early childhood. Clinically the disease is characterized by the development of more or less acute erythroblastic anemia, increase of the volume of the liver, spleen and heart and skeletal alterations. The somatic development of the patients is retarded. The face is of the Mongoloid, adenoid or Negroid types. In the cases reported by the author the disease developed during the first or second year of life. Acute erythroblastic anemia was of the hypochrome type, with anisocytosis, poikilocytosis and reticulocytosis. There was leukopenia. The number of normal erythrocytes was diminished. Immature erythrocytes were abundant in the blood. The resistance of the erythrocytes, both mature and immature, was increased in all cases. The erythropoiesis was increased (medullary hyperplasia) with predominant production of basophilic erythrocytes and reticulo-endothelioblasts. The main alterations of the bones, as shown by x-ray examination, were hypertrophic and structural changes of the cranial and facial bones, especially thickness of the diploe and striation of the cranial vault and a process of diffuse osteoporosis of the skeletal bones. A history of infection or parasitism, such as syphilis, tuberculosis, malaria or helminthiasis, did not exist in any of the patients. The author found that the resistance of the erythrocytes in the blood of the parent who transmits the disease as well as in the blood of the apparently normal brothers and sisters of the patients is increased. He also found that administration of a combined treatment of thyroid and liver extract and iron may prolong the life and improve the general condition of the patients who have atypical forms of the disease which follow a slow evolution.

Erythroblastic Anemia.—Schiappoli made an anatomopathologic study of two cadavers of children who died from erythroblastic anemia of Cooley's type. He found that the main alterations from the disease are (1) a process of general reabsorption of the bones with formation of new trabeculas, (2) diffuse hyperplasia of the reticulo-endothelial system, especially in the hemopoietic organs, and (3) hemolytic anemia, with increased medullary and extramedullary erythropoiesis. The author concludes that the disease is a hemo-osteopathy of unknown etiology, for the development of which constitution and familial predisposition are the main factors. The anatomopathologic aspects of the disease are proper. Moreover, the disease is not to be classified in any of the following groups: hemolytic jaundice, erythroleukemia, hematochromatosis and pure general hyperplasia of the reticulo-endothelial system.

Etiology of Pemphigus.—Markolf and Knauer say that cases of pemphigus neonatorum occur in which none of the known micro-organisms can be demonstrated. They recently observed an epidemic of especially severe cases of pemphigus, some of which presented the aspects of erythrodermia exfoliativa. Moreover, in older children there occur cases with mild general symptoms, which could perhaps be classified with dermatitis herpetiformis Dühring. Finally there are cases which greatly resemble pemphigus vulgaris in adults and some of which present the aspects of pemphigus foliaceus or pemphigus vegetans. The authors think that these various forms of pemphigus suggest that not all cases have the same cause. They decided to investigate whether a virus might perhaps play a part in pemphigus. In their search for virus bodies they employed several methods

give calcium salts for a long time, the effect being produced in a few hours. The author describes his observations on the effectiveness of a certain hemostatic preparation which he found ineffective in oral and only slightly effective in intramuscular injection. He also observed that the bleeding time is influenced neither by the oral nor by the intramuscular administration of calcium salts.

Clinical Experience with Diethylstilbestrol.—Felding and Møller-Christensen review reports on the biologic effect of diethylstilbestrol in rats and mice. It was observed that whereas 50 micrograms of diethylstilbestrol administered daily for ten days produced the characteristic aspects of uterine estrus in castrated rats, it was necessary to administer 100 micrograms of estrone for nineteen days to evoke the same reaction. However, on the mammae of castrated rats the effect of diethylstilbestrol proved to be only about one fifth that of estrone. On the hypophysis diethylstilbestrol had the same effect as estrone. They first give a tabulated report of the clinical histories of thirty patients with the symptoms which accompany the cessation of the ovarian function. The table gives the age of the patients, the dose, the frequency of the injections, the number of injections and the result of the treatment. As a rule a dose of 1 mg. was administered two or three times a week. In five cases the treatment was without result and in four it had to be abandoned after a few injections, as they caused nausea and vomiting. In the other twenty-five cases the result was clinically satisfactory. It was noted that as a rule the first signs of improvement appeared after the third or fourth injection. In a second table the authors present the histories of ten patients with uterine hypoplasia. In these cases the diethylstilbestrol was administered in the expectation that it might cause growth of the uterus. The size of the uterus was determined by vaginal exploration. In five cases no enlargement of the uterus could be demonstrated and in two of these the treatment had to be discontinued because diethylstilbestrol caused nausea and vomiting. In the other five cases the treatment was satisfactory, a distinct growth of the uterus being demonstrable. Since January the authors have treated fifteen other patients who had climacteric symptoms with injections of diethylstilbestrol. In all these cases the results were favorable, and nausea and vomiting was observed in none of them. The authors reach the conclusion that diethylstilbestrol may be regarded as on a par with estrone preparations. However, in about one sixth of the cases it caused nausea and vomiting, and in some instances these symptoms were so severe that treatment had to be suspended.

Vitamin K in Hemorrhagic Disease of the Newborn.—Nygaard reports sixty-six cases of hemorrhagic disease of the newborn which occurred among 9,748 newborn infants. The investigations were induced on the one hand by the observation of a physiologic transitory prolongation of the coagulation time of the blood during the first week of life and on the other hand by the fact that the coagulation time is prolonged in cases of hemorrhage and further by the fact that the hemorrhages of the newborn coincide with the period of transitory prolongation of the coagulation time. In view of recent observations that hemorrhages in cases of obstructive jaundice are preceded by a lowering of the prothrombin content of the blood, investigation was made whether the abnormal coagulation of the blood of the newborn could originate in a deficiency of prothrombin. If this was so it seemed reasonable to try the administration of vitamin K, which exerts an antihemorrhagic effect. For the determination of the prothrombin time the method of Quick was used. In order to determine the physiologic variation of pro-

thrombin during the first week of life, studies were made on thirty-one normal newborn infants. These studies indicated that a normal prothrombin time is maintained during the first ten hours after delivery but that a definite reduction of the prothrombin content becomes apparent during the second half of the first day. This low level is maintained during the following five days. From the sixth day prothrombin returns to the level found at the time of birth. Studies on the prothrombin content of some of the newborn infants with hemorrhage disclosed that in the majority of cases the onset of hemorrhage coincides with the period of transitory physiologic hypothrombinemia. Hemorrhages of the newborn generally occur when the physiologic hypothrombinemia exceeds that which is normally present at that time of life. This condition has been termed hypothrombinemia haemorrhagica neonatorum. Experiments with vitamin K revealed that the development of transitory hypothrombinemia apparently can be successfully prevented by the administration of vitamin K right after delivery. This may lead to effective prophylaxis of hypothrombinemia haemorrhagica neonatorum. Vitamin K administered to three patients with this type of hemorrhage exhibited a therapeutic effect equaling that of blood transfusion.

*Late Impairment of Spinal Cord in Curvature of Spinal Column, Especially in Those of Type of Scheuermann's Juvenile Kyphosis. G. Wretblad.—p. 617.

Scheuermann's Juvenile Kyphosis.—Wretblad points out that curvatures of the vertebral column, even those that are comparatively severe and those that develop within a comparatively short time, rarely cause severe medullary symptoms. It has been assumed that impairments of the spinal cord are entirely absent in cases of this type. Wretblad was able to observe changes in the spinal cord also in juvenile kyphosis (Scheuermann's kyphosis). He gives detailed histories of six cases, in all of which youths were involved who had performed hard physical labor; that is, they belonged to a group in which Scheuermann's kyphosis is especially frequent. An aspect that is typical of this form of kyphosis is that the development of the vertebral deformity is hardly noticed by the patient. This characteristic was observed in the described cases. Regarding the development of the medullary symptoms the author says that the patients generally observe the symptoms first on one side. In one of the reported cases the symptoms were restricted to one side for a year but then, in the course of a month, they developed with equal severity on the other side. In two cases the first symptoms were sensations of numbness and cold, but otherwise the dominating symptoms were weakness and lack of steadiness in the legs. In some of the cases weakness of the bladder or constipation developed. Examination revealed in one of the cases a mild spastic paraparesis and in the other cases a severe one which prevented walking entirely or almost entirely, also a reduction in sensitivity, the upper limits of which correspond to the medullary segment of the vertex of the kyphosis. Myelography indicated that at the vertex of the kyphosis there existed an obstruction in the circulation of the spinal fluid, in that the dura was probably pressed against the spinal cord. Opening of the dura counteracted this obstruction. Laminectomy and leaving the dura open produced favorable results in three cases in which the medullary symptoms were of a comparatively recent date. In another case, in which the medullary symptoms had existed for several years, death followed a short time after the operation and the necropsy revealed that irreparable medullary changes, caused by the kyphosis, had developed previous to the operation. The author thinks that it cannot be doubted that the kyphosis is the cause of the medullary symptoms. He cites factors in support of this contention.

FATALITY RATES IN THE TREAT- MENT OF 998 ERYSIPELAS PATIENTS

THE INFLUENCE OF SULFANILAMIDE

ARCHIBALD L. HOYNE, M.D.

A. ALVIN WOLF, M.D.

AND

LEONA PRIM, R.N.

CHICAGO

Hippocrates gave a fair description of erysipelas and Galen more closely defined it. Since then various forms of treatment have been as numerous as the centuries that have elapsed. That this disease cannot be ignored as a cause of death is shown in table 1. It may be noted that for the first year of the quinquennium, with 196 patients, the fatality rate was 17.3 per cent, whereas in 1938 among 141 patients the death rate was only 2.1 per cent. Even the last named figure, which includes those of all ages, is of sufficient significance to view with alarm patients in the two extremes of life when the death rates are highest. Surgical patients and those suffering from chronic diseases or conditions in which malnutrition is an important factor are also serious, because in such groups fatality rates are often very high. It is for these reasons that we believe that a reduction of 87.8 per cent in the mortality for erysipelas within a period of five years is an accomplishment worthy of mention.

In table 2 the patients are divided according to age and sex, the number of deaths for each of the age groups and by sex, and with the corresponding fatality rates. It may be noted that approximately 60 per cent were males and 40 per cent females. These proportions are in accord with common observation. Furthermore, it may be seen that the fatality rate for males is almost exactly double the corresponding rate for females, the precise figures being 12.1 per cent in the former instance and 6.3 per cent in the latter. In our total group of patients, fifty-three were under 1 year of age. It is at this period of life that fatal terminations often reach great heights, ranging from 50 per cent upward. Therefore we believe that our fatality rate of 37.3 per cent for this group is satisfactory. Here the question of sex is again of interest, for whereas the patients were almost equally divided in this respect there were 20 per cent more deaths among the males. The rate of 45.8 per cent among those over 76 years of age is not surprising. Although the latter group is small, comprising but fifteen patients with four times as many males as females, it is again noteworthy that there is a pre-

ponderance of deaths among the males when compared to the females, the ratio in this group being 7:1.

Table 3 is a summary of patients admitted to the hospital according to the seasons of the several years. This distribution fulfils usual expectations concerning the months in which erysipelas displays its high and low incidence. The higher trends of the disease in the spring and winter is clearly evident and the percentage of patients is approximately the same for these two seasons in each of the five years. Frequently in years past, however, it has been our experience that by far the greatest number of erysipelas patients were admitted to the hospital in March and April. Not only was the number of patients greater in the spring but most deaths occurred in this season.

The chart is a graphic representation of the trend of erysipelas mortality at the Cook County Hospital for the period 1929-1938. The sharp decline we believe is not altogether due to variations in the severity of this disease but is in fact attributable in a large measure to improved methods of treatment.

Comparative mortality, 1929-1938.

We have previously referred to the influence of age and sex on the prognosis of the average attack of erysipelas. Other factors affecting the outcome pertain to the site of infection, as is well known. In table 4 there will be found a division of our patients according to the manner of infection and the areas involved. The fact that so large a proportion of the patients are classified as unknown for the mode of infection is not surprising. One of the most frequent ports of infection is the nose, as a consequence of abrading the mucous membrane of the nostril by means of the finger nail. Likewise, in a similar manner the ear sometimes serves

as a port of entry when abraded by an exploring toothpick, match or fingernail. Under such circumstances the patient invariably denies a history of trauma. Furthermore, because of the accessibility of the nostrils, the ears and any portion of the face or even head, we find that such areas provide the soil for an attack of

erysipelas in more than 85 per cent of cases as a rule. In our own series the rate was 90.1 per cent. The incidence of facial erysipelas exclusive of other portions of the head was 86.6 per cent. There were but 7.4 per cent of all cases in which erysipelas primarily affected the extremities; the trunk was the original site of infection in 2.4 per cent.

Much could be written about the multiplicity of methods advised in the past for the treatment of erysipelas. Local applications, including heat, cold, ointments and mechanical measures such as elastic bandages and collodion bands have been used. Internal medications have embraced a great variety of drugs. There have been antistreptococcus serums and more recently erysipelas antitoxins. Whole blood, intramuscularly or intravenously, has been advocated. Convalescent human serum has also been recommended. Roentgen irradiation and ultraviolet rays have at times

been in the ascendancy. Various degrees of success have been reported irrespective of the therapy applied. In table 6 we have indicated the use of a number of the measures mentioned for the purpose of illustrating what may be anticipated in respect to recovery. Nevertheless we realize that many of these groups are too small to afford an accurate basis of conclusion in respect to efficiency or lack of therapeutic value for the remedies used.

Prior to the introduction of sulfanilamide, we believed that the use of ultraviolet rays was probably the most successful agency for treatment that had been followed in the Contagious Disease Department for many years past.

It may be seen at the end of table 6 that 162 patients were treated with sulfanilamide. Of that number 132 received such therapy during the year 1938. The status of these patients with regard to age and sex is set forth in tables previously referred to. The fatality rate for all admissions in 1938 was the lowest ever recorded in our experience (2.46 per cent) and is not confined to any single group. It includes all from infancy to

old age and both surgical and those with debilitating diseases who are so commonly a prey to erysipelas. There are no fatal instances excluded from our statistics regardless of how soon death occurred after the patient entered the hospital.

We believe it a matter of interest to record the principal diseases and conditions which were present in our erysipelas patients. This has been done in table 5. Here

are listed not merely the complications which were contributory to a fatal termination but also diseases and conditions which were present prior to the attack of erysipelas and therefore greatly increased the hazards attending the illness. We have enumerated the respective totals, indicated the number of fatalities for each and shown fatality rates for the various groups in which pathologic conditions, not necessarily related to erysipelas, were present. The last column of table 5 shows the part played by the various complications or conditions in contributing to the total number of deaths. It is evident from the figures, as might be anticipated, that bronchopneumonia is the most important complication causing death and that those patients who suffer from organic heart disease prove to be unusually poor risks when subjected to attacks of erysipelas.

For 378 patients treated by Fox,³ the fatality rate was 9.52 per cent. The patients were divided into two groups, one being treated by serum and the other without serum. There was no significant difference in the fatality rates, which were 8.8 for the former and 9.7 for the latter.

More recently Snodgrass, Anderson and Renne⁴ described the treatment of 242 patients who were given sulfanilamide. Their fatality rate was only 2.06 per cent. It is rather interesting that the latter figure corresponds closely with our own group of 162 patients when sulfanilamide was used with a fatality rate of 2.46 per cent. These figures are particularly impressive to us when we consider the years 1929-1933. For that period 1,193 cases were reported by one of us⁵ with a fatality rate of 13.4 per cent at the Cook County

COMMENT

In 1930 Ude and Platon¹ reported on the treatment of 402 erysipelas patients, who were divided into six groups according to the method of treatment adopted. Fatality rates for the respective groups varied from 23.8 to 7.6 per cent. Magnesium sulfate locally, roentgen irradiation, ultraviolet irradiation and erysipelas antitoxin constituted the chief form of therapy in each of four groups; in the remaining two groups combined forms of therapy were used. Their lowest fatality rate was attained by the employment of ultraviolet rays.

Symmers and Lewis,² reporting on the treatment of 4,698 patients with erysipelas antitoxin, had a fatality rate of 7.2 per cent.

Hospital. Consequently, it is our conclusion that sulfanilamide is the most effective form of therapy thus far used in the treatment of erysipelas.

Relation of Physiology to Medicine.—The obligations of physiology to medicine are twofold: to teach the student bent on the practice of medicine the normal functions of the human body, and in doing so to train him as an accurate observer and thinker; and to lay a foundation upon which the house of medical science shall erect itself. If you will, you may weld the two together and say that in its relation to medicine the function of physiology is to gather, classify, and spread knowledge and methods of studying the normal functions of the animal body.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

SURGICAL ASPECTS OF CARCINOMA
OF THE LARGE BOWEL

HARVEY B. STONE, M.D.
AND
SAMUEL McLANAHAN, M.D.
BALTIMORE

Well informed surgeons today have learned much about carcinoma of the colon and rectum. They know that the disease is often curable but that delayed diagnosis forces almost one half of the victims to seek surgical help in an incurable state. They have been taught the importance of certain characteristic symptoms which at once arouse suspicions demanding thorough investigation. In addition they know from precept, if not from experience, the essential value of abdominal and especially of rectal palpation, of proctoscopy and of sigmoidoscopy. Furthermore, they appreciate the accuracy of diagnosis of the colonic lesions which is possible in the hands of efficient roentgenologists and acknowledge the great contribution which roentgenology has made toward early diagnosis. With these concepts firmly in mind, modern surgeons are profoundly interested in the practical surgical approach and it is to such a consideration that these remarks are addressed.

TABLE 1.—Carcinoma of Large Intestine: Operability Rate

	Cases	Resections	Operability
Right.....	25	21	84.0%
Transverse.....	18	14	77.7%
Left.....	88	62	70.4%
Rectum.....	102	69	67.6%
Total.....	233	166	71.2%

The group of 233 cases on which the accompanying statistics are based represents patients operated on by the authors over an eighteen year period in four hospitals and drawn largely from the private practice of the senior author. These statistics correspond in general with those from other clinics, and while the group of cases is not large enough for conclusive evidence it does serve to focus attention on certain specific principles which we desire to emphasize.

OPERABILITY

Operability rates depend on many factors and may reflect both the type of patients in a given series and the attitude of the operator toward radical resection. An extension of operability will necessarily result in a higher mortality rate, but mortality rates in cancer surgery should be viewed with a less critical eye than mortality rates in nonfatal diseases. As Dr. J. M. T. Finney has so often remarked, exploration in these cases represents "the last call." The patient must be given his chance, and indeed he is usually glad to take his chance, if it is a reasonable one. Our operability rate over the years, based on the percentage of resections in the cases in which operation was performed, has been 71.2 per cent (table 1). It is interesting to note that it has been highest for the tumors on the right side and has gradually decreased as successive portions of the large intestine are considered. Thus the percentage of operability for the right colon is 84, for the transverse colon 77.7, for the left colon 70.4 and for the rectum 67.6.

In the presence of demonstrable visceral or peritoneal metastases it is often justifiable, and indeed good judgment, to remove an operable obstructing lesion. This practice has enabled a number of patients to live comfortably for periods of two and three years before succumbing to the disease. In other instances, however, there has been disappointment when local recurrence with obstruction has supervened in a few months.

In a number of cases it has not been possible to ascertain at once the operability of a given tumor without first making a careful, discreet beginning of resection. In this way several growths which at first inspection and palpation would necessarily be considered inoperable have finally been found removable. On the other hand it has as often been necessary to withdraw when the operator was convinced that further attempts at extirpation were unwise.

THE INOPERABLE CASE

Statistics generally, including our own, show a slightly higher mortality rate for simple exploratory or palliative procedures than they do for the resections (table 2). Nevertheless, in the presence of an inoperable obstructing lesion the surgeon who would do what he can to prolong his patient's life is confronted with the necessity of performing some palliative operation. The choice is likely to be either a short-circuiting anastomosis, a colostomy or, in the case of a low rectal growth, local destruction of the lesion. The latter procedure has been carried out at times with the curet, the actual cautery or the desiccating current. Such desiccation or diathermy applied to a frank carcinoma should, in our opinion, be limited to inoperable growths and not used as the procedure of choice, as has at times been advocated. A strange exception appears in this series when it is shown that thirty-three exploratory or palliative operations in connection with rectal cancers were performed without a hospital death.

For the inoperable low sigmoid or rectal growth which at the time of exploration is not obstructing, one of us (H. B. S.) has advocated and practiced for many years a procedure termed precolostomy.¹ A knuckle of sigmoid proximal to the growth is brought out through a short left McBurney incision and sutured to the skin. This maneuver need not interfere with the fecal flow but is in effect the first stage of a sigmoidostomy. The second stage, consisting of an incision in the intestinal wall, can be performed in the near or distant future, when necessity dictates, or may never need to be done at all.

In the presence of an inoperable tumor and more especially in the presence of a recurrence, irradiation is often helpful. Adequate roentgen therapy and the implantation of radium or radon may contribute much to the patient's comfort.

PREOPERATIVE MEASURES

It is a fortunate fact that the majority of patients present themselves in a condition which permits preoperative preparation. Two complications, however, may require prompt operation and indeed may so obscure the diagnosis as to make it clear only when exploration has been carried out. The first of these, acute obstruction, occurred ten times in our series, while the second, perforation accompanied by abscess formation, occurred six times. Of these sixteen patients, five died after the primary procedure and one after the second stage of resection. Among other serious com-

Read before the Section on Surgery, General and Abdominal, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

plications which may exist are anemia, dehydration and dietary deficiency states. The indication is clear to correct these complications by appropriate means as far as one is able.

Partial intestinal obstruction represents the major problem to be solved before the patient is fit for the removal of his growth. It is our firm belief that in the majority of cases the bowel can be safely and satisfactorily decompressed and cleansed without recourse to any sort of enterostomy. To obtain such a cleansing, a week or longer must be allowed and a definite regimen must be followed. Our practice has been to prescribe a daily saline cathartic, a daily cleansing enema, liquid petrolatum and a high carbohydrate, low residue diet. Should it appear after a reasonable interval, however, that these or similar measures have been ineffective and that the patient continues to exhibit signs of partial obstruction, surgical drainage of a proximal segment should be carried out.

In addition to acute obstruction of the intestine, to perforation of the growth and to ineffective conservative measures, preliminary drainage of the bowel may also be called for with patients who are poor risks by reason of age or of associated diseases. This is especially true of tumors of the right half of the colon, in which the drainage may consist of an ileocolostomy, thereby completing the anastomosis feature of the resection. While in no sense criticizing others who use preliminary drainage as a routine procedure, we are convinced that it should be reserved for special indications and we predict

some type of preliminary bowel drainage and that in three of the eleven drainage was done elsewhere.

We have had no experience with intraperitoneal vaccination and do not believe at this time that the evidence is conclusive enough to warrant its adoption. The reports, however, are being followed with deep interest.

Fig. 2.—The diseased segment has been removed and the ends of the bowel are being brought together for anastomosis. The posterior layer of continuous silk has been laid. The handles are omitted for the sake of clarity.

Fig. 1.—Resection of the sigmoid colon and aseptic end to end anastomosis. Stone clamps being used. The growth with a generous margin of intestine and with adjacent mesentery is about to be resected. The handle of each clamp secures the blades in their closed position. Two other clamps are to be placed on the ends of the segment to be resected.

that experienced operators will use it with less frequency in the future. The preference for one stage operations in this series is clearly demonstrated when it is shown that only eleven of the 166 resections were preceded by

The surgeon must employ the kind of anesthesia which he has found most satisfactory for abdominal surgery of this type. Just as it is the man behind the splint that counts, so it is the person administering the anesthetic who is of prime importance. The preference in these cases has been for general anesthesia, usually gas-oxygen and ether, and more recently cyclopropane preceded by a basal anesthetic of the barbituric acid series.

OPERATION

The ideal operation for malignant lesions of this area has been well defined by Dixon² as "one in which complete removal of the growth is accomplished, normal function is preserved or restored, and recovery is effected." We should like to supplement this statement of sound principles by adding that the ideal operation also is one which assures the earliest recovery of the patient compatible with safety and affords a minimum of pain and discomfort.

In selecting the type of procedure for lesions in the colon, the principle generally adhered to in this series of cases has been aseptic end to end anastomosis following an adequate resection of the growth and its adjacent mesentery. Rankin's obstructive resection³ has been employed a number of times, however, as have open anastomoses, end to end, side to side and end to side. Allen⁴ has given a clear statement of the important points to be observed in performing an anastomosis and has emphasized the advantages of an

aseptic type of union. While the open type may under certain circumstances be easier, and while in the lateral variety there may theoretically be less danger to the blood supply of the intestinal wall, still we believe that the advantage in avoiding the probability of contamination makes aseptic end to end anastomosis more desir-

able. In our own experience, seventy-one cases of aseptic anastomosis of the Parker-Kerr or clamp type yielded a mortality of 11.2 per cent, while nineteen cases of open anastomosis yielded a mortality of 26.3 per

cent (table 2). It is true that a number of the latter failures were instances of difficult, low sigmoid growths in which a "tube anastomosis" was done in an effort to utilize a short rectal stump and avoid colostomy. As a result we believe that, unless an aseptic type of anastomosis can be satisfactorily performed at this low level, no open type should be attempted. Instead, a permanent colostomy should be made.

As a method of performing aseptic end to end anastomosis, we have been using for almost three years a special set of clamps described elsewhere.⁵ These clamps are characterized by their narrow blades and detachable handles. The detailed technic of their use

5. Stone, H. B.: Method of Intestinal Anastomosis with New Clamp, Surg., Gynec. & Obst. 65: 383 (Sept.) 1937.

has been given by Owings and Stone.⁶ Within the past two years at the Baltimore City Hospitals there have been performed fifteen consecutive one stage resections of the sigmoid utilizing this technic. The cases have all been done by the resident staff and there have been no deaths.

Mayo and Simpson⁷ have recently advocated resection and primary anastomosis in the transverse colon and have presented thirty-six cases with an 11.1 per cent mortality for comparison with ninety-five cases of extraperitoneal resection having a mortality rate of 20 per cent. They emphasize the important secondary considerations of avoiding repeated operations and long hospitalization.

Concomitant decompression in the absence of preliminary drainage is practiced as a routine by many surgeons in the case of a primary anastomosis. It has not been performed in this group of colon cases and our conclusion on reviewing the data is that it should be used more frequently. In low sigmoid anastomoses, however, it has been the practice to introduce a rectal tube and pass the tip several inches proximal to the anastomosis, thereby giving drainage to the proximal segment.

Fig. 4.—The anastomosis is completed by laying a row of mattress sutures of silk, which serve also to invert the original knots. The rent in the mesentery is closed.

In considering the management of malignant growths in the rectum, one of the most perplexing problems is that of the solitary, sessile polyp having malignant characteristics. If grossly and microscopically there is

no invasion of the muscularis mucosae, our policy is to be content for the time being with local excision. The patient is carefully observed and, if there is evidence of recurrence of the polyp, excision is again performed. When histologic evidence is present that epithelial proliferation has invaded the rectal wall, a diagnosis of rectal cancer is made and the appropriate treatment instituted. Of nine instances of malignant polyps, one patient, followed for nine years, has had three recurrences at the site of excision, none of them invading the rectal wall. He is now well, without evidence of disease. Two other patients have required radical excision of the rectum.

The classic work of Miles,⁸ in our opinion, still forms the basis of logical attack on rectal cancer. Although the work of Brown and Warren⁹ indicates that visceral metastases depend largely on blood vascular invasion by tumor cells, the evidence from Gilchrist and David¹⁰ that lymphatic nodes may be secondarily involved without showing gross change strongly supports the principle that radical removal of lymphatic structures must not be compromised. This leaves the combined abdominoperineal operation as the procedure of choice for the properly selected case. Various modifications of the original operation have been perfected and described by D. F. Jones,¹¹ Rankin,¹² Lahey,¹³ Lahey and Cattell,¹⁴ T. E. Jones,¹⁵ Babcock,¹⁶ and others. Perineal resection of a low lying growth, with or without colostomy, sacrifices something in leaving behind potentially involved lymphatics but offers a less radical operation for the patient who is a poor risk. The surgeon must have a variety of procedures available.

The preference throughout this series has been for one stage abdominoperineal resection (table 3). In 1937, twenty-nine consecutive cases were reported¹⁷ with a hospital mortality rate of 10.3 per cent. These are included in the present total of forty-two cases with a mortality rate of 16.6 per cent. This higher figure represents the extension of the operation to include several bad risk patients with a resulting elevation of

ing the perineal part of the combined operation, the dorsal lithotomy position has been employed and only rarely has the coccyx been excised.

POSTOPERATIVE CARE

Either during or immediately following a resection of the large bowel, the patient should receive as a routine procedure a transfusion of blood. Other intravenous fluids should be given in large enough amounts to insure an adequate urinary output, as suggested by

Maddock and Collier.¹⁸ Conscientious care on the part of the surgeon and his hospital organization can do much toward avoiding and lessening the threatened complications. Shock and infection as well as cardiovascular, pulmonary and urinary complications may be expected and if they appear should be treated promptly. Aluminum paste¹⁹ on the skin has proved a great help in preventing irritation from fecal drainage in the early weeks. Instruction on the part of the surgeon is necessary in helping the patient to care for his colostomy.²⁰ Only by sending out patients properly trained in managing their colostomies will it be possible to dispel the ordinarily unjustifiable fear of colostomy which is held by many physicians as well as by the public at large.

CAUSE OF DEATH

Among the 166 resections there were twenty-three deaths, or a mortality rate of 13.8 per cent. In the small group of fifteen two stage operations there was only one death, a rate of 6⅔ per cent, while in 151 one stage cases there were twenty-two deaths, or a rate of 14.5 per cent. In sixty-three cases of one stage colonic resection completed with an aseptic anastomosis there were eight deaths, or a mortality of 12.6 per cent.

In considering the twenty-three fatalities associated with resection, thirteen, or 56.5 per cent, of these fatalities can be directly attributable to the operative procedure, there being eleven cases of peritonitis and two cases of intestinal obstruction (table 5). The remaining ten cases were due to cardiovascular, pulmonary, cerebral or diabetic complications. The incidence of peritonitis stresses to us the importance of an aseptic type of anastomosis, because many of these deaths occurred in the open type, and stresses the importance of more frequent employment of concomitant bowel drainage.

SUMMARY AND CONCLUSIONS

Modern surgeons, who are well informed with regard to symptoms and diagnosis of carcinoma of the colon and rectum, are especially interested in the practical surgical approach.

Operability rates affect mortality rates, but the latter must not be viewed too critically in cancer surgery. Our own operability rate for the large intestine has been 71.2 per cent.

It is often justifiable to remove an operable obstructing lesion in the presence of visceral metastases. Before the operability of a tumor can be determined finally, it may be necessary occasionally to make a careful, discreet beginning of resection.

In addition to the usual palliative procedures for an inoperable tumor, precolostomy has been used frequently for low sigmoid or rectal growths, thereby obviating in many cases the immediate formation of a fecal fistula.

The intestine can be cleansed safely and satisfactorily in the majority of cases without recourse to any sort of preliminary enterostomy. Acute obstruction, perforation, ineffective conservative measures, age and associated diseases, however, may be indications for preliminary surgical drainage of the bowel and a two stage procedure. A one stage operation has been preferred whenever possible in this series.

While a variety of procedures are available for the colon, aseptic end to end anastomosis following an adequate resection has been the operation of choice. Seventy-one such cases yielded a mortality of 11.2 per cent. Concomitant decompression in the absence of preliminary drainage should be employed occasionally.

Local excision of a solitary malignant rectal polyp not invading the rectal wall is sufficient, provided careful observation of the patient follows. Radical operation should be performed if and when invasion of the rectal wall is determined.

Abdominoperineal resection is the logical operation for carcinoma of the rectum and in this series has been carried out in one stage. Perineal resection has been used for low growths in patients who are poor risks. Instruction of the patient by his surgeon with regard to the care of his colostomy is of the utmost importance.

While only 56 per cent of the deaths are directly attributable to the operative procedure, the incidence of peritonitis is high enough to stress the importance of an aseptic type of anastomosis and the desirability for more frequent employment of concomitant bowel drainage.

18 West Franklin Street—108 East Thirty-Third Street.

ABSTRACT OF DISCUSSION

DR. JAMES D. RIVES, New Orleans: Three features strike me as being noteworthy: first, the large percentage of radical operations, which I think it fair to credit largely to the high level of intelligence among the professional friends and the clientele of the authors. The frequency of radical operations in my practice is less than 50 per cent; second, the high frequency of resection with primary anastomosis, which must be credited to their supreme confidence in their operative methods; and, third, the low operative mortality, which justifies that confidence. I have believed that for most surgeons multiple stage operations are safer and that this is particularly true of obstructive resections. Proximal decompression adds materially to the safety of resection with primary anastomosis of the left half of the colon even when no obstruction exists. However, the brief period of disability and the much greater comfort of patients who have had a one stage operation have a strong appeal, and there is no doubt if the mortality is not excessive that this type of procedure is preferable. The results reported by Drs. Stone and McLanahan are at least as good as those I get with multiple stage operations, and for some time I have been attempting to follow their lead. The preoperative preparation is of paramount importance. If the intestine is properly prepared and a careful technic employed, the minimal amount of peritoneal soiling that occurs, even in an open anastomosis, is quite unlikely to cause general peritonitis or even local abscess formation. There is, however, great danger that such soiling may produce a severe or even fatal anaerobic infection of the wound. Aseptic anastomosis is therefore desirable. The technic reported by Drs. Stone and Owings, with the clamp devised by Dr. Stone, is a most satisfactory method in my hands. However, I want to emphasize the fact that the result depends less on the method used than on the manner of its execution. The greatest danger of primary anastomosis is peritonitis, and this results usually not from contamination during the operation but from subsequent leakage at the suture line. This may result from a number of different causes, among which avitaminosis and plasma protein deficiency are probably prominent. Technical difficulties have impressed me most. Obviously the suture line must be gas and water tight, which requires very careful suturing when no through and through suture is placed on the wound margins. If, as the mesentery is dissected during removal of the enlarged nodes, the main vessels are traumatized, thrombosis may occur with gangrene, perforation and death.

DR. LELAND S. MCKITTRICK, Boston: One cannot but be tremendously impressed with the report of so high an operability and so low a mortality. It is difficult to take issue with so excellent a report. On the other hand, not all of us have had the experience of the authors and must depend on the procedures that are safest in the hands of the average surgeon. I have looked up our cases at the Massachusetts General Hospital, where the operations are done not by one or two men but by a large group of well trained surgeons. Prior to 1932 most of the resections of the right colon were done in one stage, probably because of the influence of the late Dr. D. F. Jones, who did most if not all these operations in one stage. In forty consecutive colectomies on the right side prior to 1932, thirty-seven were done in one stage with a mortality of 30 per cent. There were no deaths resulting from the three two stage operations. These forty cases represented 49 per cent of all the cases seen. Since 1932, largely through the influence of Dr. A. W. Allen, many more two stage colectomies on the right side have been done. Of the thirty-eight operations done during the past seven years, twenty have been done in one stage, still with a mortality of 30 per cent. The remaining eighteen have been two stage operations, with a mortality of 22 per cent. It is of significance, however, that not only is the mortality in the two stage group lower but the operability during the past seven years has been 71 per cent rather than 49 per cent, as in the preceding period. It would seem, therefore, that by doing the operation in two stages rather than in one the surgeons at the Massachusetts General Hospital can operate on a higher percentage of patients with carcinoma of the right colon with a lower operative mortality. I know that I can successfully remove the right colon in poor risk patients by doing a preliminary lateral anastomosis between the terminal ileum and the transverse colon and then at a second stage removing the intervening bowel, whereas if I attempted to do the resection in one stage certain of these patients would die. The thing that bothers me, however, is this: Because I can more safely operate on poor risk patients in two stages, does it follow that the younger good risk patients with no obstruction can also be operated on more safely in two stages than in one? Of this I am not convinced. I still do a certain number of one stage operations because I believe that the operation in one stage holds certain advantages over the two stage procedure, but I select these patients very carefully.

DR. HENRY K. RANSOM, Ann Arbor, Mich.: I recently reviewed the records of patients with carcinoma of the colon treated at the University Hospital during the past ten years, being particularly interested in the results of treatment of carcinoma of the right colon. A variety of operative procedures were employed. The operative mortality for right hemicolectomy was high. When these cases were considered according to the type of operation performed, (1) the one

stage operation with resection and primary suture anastomosis, (2) the modified Mikulicz procedure or obstructive resection and (3) the two stage operation consisting of preliminary ileocolostomy, with resection of the right colon at a second stage some three weeks later, a rather striking difference in operative mortality was noted. In the majority of cases a one stage operation was performed, and this procedure was attended with the highest mortality. The group of patients treated by obstructive resection was considerably smaller and therefore these statistics are less valuable. However, the mortality in this group was almost as high as in the one stage group. On the other hand, in a small number of cases dealt with by the two stage operation the operative mortality was approximately only one half. We decided to utilize the two stage operation more or less as a routine, and during the past few months seven right hemicolectomies for carcinoma have been done by this method. All the patients have had a satisfactory convalescence and there were no deaths. In the past an important argument in favor of the two stage operation has been the assumption that the first stage provides the peritoneum with increased resistance to infection so that the second stage may be done more safely. Our experimental results showed that, while a preliminary operation such as an intestinal anastomosis or colostomy does confer a certain degree of immunity to infection on the peritoneum, the amount of protection thus afforded is relatively slight and does not constitute an important argument in favor of the two stage procedure. While the application of the results of experimental surgery to the human patient may always be open to question, nevertheless it would seem that if one is chiefly interested in increasing the resistance of the peritoneum to infection this can be accomplished much more effectively by the use of peritoneal vaccination with Steinberg's colibacterin or a similar substance.

DR. CLAUDE F. DIXON, Rochester, Minn.: The authors have emphasized many pertinent points regarding colonic operations. Whether such operations should be carried out in one or in two stages seems to me to be dependent on many factors, the most important being the condition of the patient, the situation and type of the lesion and the custom or usual practice of the individual surgeon. One might compare single and multiple stage operations on the colon and rectum to the management of appendicitis; that is, one surgeon may present excellent results from having operated on the appendix regardless of the phase of the disease, while another may argue that this method is wrong and may present a report of excellent results in an equal number of cases in some of which he used an entirely different plan, namely deferred operation. Suffice it to say that if Drs. Stone and McLanahan and their confrères can continue to obtain such good results in one stage operations perhaps they should hold to their present method of management. Like McKittrick, I was trained, for the most part, to employ the multiple stage plan. If a surgeon completes the operative procedure in a single stage with a disastrous result he wonders what might have happened had he employed a two stage or a three stage method. During the past seven years, instead of the combined abdominoperineal resection I have carried out a procedure in which I reestablish continuity of the bowel. First, a colonic stoma is provided in the transverse or descending colon; then this is followed in two or three weeks by an anterior resection, at the completion of which, end to end anastomosis is effected. The superior hemorrhoidal vessels are sacrificed, the entire pelvic colon is removed, as in the combined abdominoperineal operation, and anastomosis is made between the lower portion of the descending colon or first part of the sigmoid and the rectum. This procedure is just as radical as the combined type of operation except that the rectum is preserved. Malignant processes in the colon rarely spread downward; therefore why is it not justifiable to preserve the rectum? In more than 300 cases in which this procedure has been employed the mortality rate has varied between 8 and 12 per cent. It is my opinion that the morbidity and mortality are much less with this procedure than with the combined operation, and in addition the function of the rectum is not disturbed, since the procedure is carried out through an abdominal incision. Sacrificing the superior hemorrhoidal vessels has not caused impairment of the circulation in

the remaining segment of rectum. In cases in which this method is employed it is possible to feel the anastomosis easily by digital examination of the rectum.

DR. FRANK H. LAHEY, Boston: I do not think there will be much disagreement between men on a subject such as this when they have all had considerable experience with it. The disagreements will be largely limited to methods of procedure. Drs. Stone and McLanahan would like to do a great many of these operations in one stage. Dr. McKittrick and some of the other men who have spoken might be considered in between their position and mine, and I represent the group who consider it advisable to remove all abdominal colons in two stages. In my clinic all abdominal colons (not rectums) are removed in two stages by the modified Mikulicz procedure which I have described. I am sure that some of them could probably be done in one stage. If it is a matter of personal reaction on my part certainly all my surgical associates agree with me in the position that the only way to ascertain whether or not the operation can be done in one stage is to risk the matter of a fatality from leakage after an anastomosis. It must be admitted, I feel sure after a large experience with this modified Mikulicz procedure, that the danger of leakage does not exist with that procedure. I know from my own figures that this two stage modified Mikulicz procedure, together with staggering of the terminal loops and immediate decompression as I suggested in my first description of this method, has definitely lowered our mortality rate and widened our operability rate. The operability rate at my clinic last year was 89.9 per cent and the mortality rate 10 per cent for all the cases of carcinoma of the colon and rectum. One of the points I want to make and which I think should be kept in mind is that cases are being rejected today which should not be rejected. One should carefully differentiate between the case in which there is extension from metastases or peritoneal spread and the case in which there is a contact carcinoma. We have had a number of patients who have had a contact carcinoma between a carcinoma of the rectosigmoid and the back of the uterus; in such a case one could remove the uterus, the tubes and the ovaries, together with the rectum. We have had cases in which there has been a contact carcinoma on the top of the bladder from a carcinoma of the sigmoid resting on top of it, but there were no metastases. The top of the bladder could be safely removed, together with the sigmoid. We have had cases of contact carcinoma on the small intestine from a malignant growth of the right colon in which several inches of small intestine has been resected together with the colon and often results of examination of the glands have been negative.

DR. HARVEY B. STONE, Baltimore: There stand out in the discussion three points that deserve emphasis. The first comprises the valuable comments made by Dr. Rives and Dr. McKittrick on the basic principles of anastomosis. As Dr. McKittrick has said, Dr. Dan Jones of Boston was one of the first to emphasize these principles, and he pretty nearly covered the entire field. There has been little to add to his comments on the importance of adequate vascular supply, the avoidance of tension in the suture line and the removal of pressure from within the bowel subsequent to the anastomosis. Dr. McLanahan and I feel that, in addition to the points emphasized by Dr. Jones and referred to by Dr. Rives and Dr. McKittrick, another important factor is the avoidance of gross soiling, which may be approximated at least by the adoption of some form of aseptic technic. The second issue, which has been commented on by every one of the discussers and which was one of the important points we had in mind in the presentation of this paper, is the merit, or otherwise, of a single or multiple stage operation. Dr. McKittrick approached his present position from beginning in the one stage group. I approached my present position in exactly the opposite path, beginning as a routine two stage operator. It is quite apparent from the comment which has been made, with which we heartily agree, that the decision in any case as to the selection of these various methods of attack must depend on a number of varying factors: the patient, the lesion, the surgeon, his experience, his predilections. The plea that we make is that the one stage operation has a field of usefulness. Quite candidly, I think that perhaps we have

pushed it too far and that in the future we shall be inclined to do more multiple stage resections than we have done in the last few years. But I should like to see those who are confirmed two stage operators equally flexible and ready in suitable cases to attempt the one stage procedure, which in spite of all the admitted objections has definite and specific advantages of its own which are not possessed by any type of two stage operation. I would plead for the use of the one stage operation in proper cases and for a point of view of adaptability and flexibility in the decision of this whole matter. The last point that I should like to reiterate is the question of what to do with the small isolated polyp in the rectum, which clinically seems benign but which on microscopic examination shows evidences of malignancy, when the malignant condition has not yet broken through the muscularis mucosae. Our procedure has been to do a local removal and to watch the patient for evidence of recurrence.

TUBERCULOSIS CONTROL

ROBERT E. PLUNKETT, M.D.

General Superintendent of Tuberculosis Hospitals, New York State
Department of Health, Division of Tuberculosis

ALBANY, N. Y.

The behavior and control of tuberculosis, whether in the individual suffering from the disease or as a community problem, depend on the proper control and disposal of bacillus-laden sputum. Control the sputum and spread is prevented; neglect this measure and cases multiply.

Although the tubercle bacillus is the specific cause of tuberculosis, it must be recognized that other factors contribute to both the epidemiology and the pathogenesis of the disease. These contributing factors may be grouped under two headings—the constitutional and the environmental. Of these the environmental factors are legion and appear to play a more common part in disease development than the constitutional. Recognizing the variables which may influence the disease in certain racial, industrial and social groups, it can be stated that contact with a sputum positive case, with its opportunity for infection and reinfection by frequent and massive doses of tubercle bacilli, appears to be the most important single factor.

Keeping in mind the significance of bacillus-laden sputum, the following procedures are essential in the administration of control measures: the reporting and registration of cases of tuberculosis, active and progressive case finding, the segregation and treatment of patients suffering from the disease, domiciliary supervision of families in which tuberculosis is or has been a problem, rehabilitation of cases, the follow-up of all cases and contacts, and financial assistance to needy families in a manner free from the stigma of pauperism. Equally important is the periodic appraisal and evaluation of procedures and services, from the point of view both of administrative economy and of more effective extension of our knowledge of the epidemiology and pathogenesis of the disease.

CONTROL BY DIVISION OF TUBERCULOSIS

In translating the preceding into administrative practice in New York State, the responsibility of the program is placed in the Division of Tuberculosis. There are fifty-seven counties in upstate New York with an estimated total population of 6,080,444. These counties vary in population from 3,929 to 813,786. The death

rate from tuberculosis has dropped from 161.5 per hundred thousand in 1900 to 44.7 in 1938.

The purposes of the division may be considered as threefold: first, direct service to the people examined and studied, their families and communities; second, research through the acquisition of data, their classification and interpretation, and third, education of the public and the medical profession. A considerable part of the general administration and supervision of the work performed by local health districts and nursing services is the responsibility of our district state health officers, of whom there are twenty. Problems which require specialized consultation or advice are handled either jointly with a member of the division staff or individually. Knowledge of the scope and extent of the disease problem in a community is as essential to the health officer as the extent and character of a lesion in an individual patient are to a clinician. Such knowledge may be acquired from detailed morbidity and mortality data. By complete checking of detailed information on death certificates regarding residence and so on and prompt and complete reporting of existing cases, the health officer is able actually to take stock and be guided wisely in his administrative program. To provide such opportunities, the reporting of tuberculosis cases is constantly being promoted by both the district offices and the division staff. Consequently the tuberculosis report cards are routed, except for our largest cities and county health district areas, through the office of the district state health officer. Each district officer maintains a case register for all reported cases in his district. The name, address, sex, age, clinical stage and sputum status are all catalogued by the use of colored flags in a visible index file for ready reference in follow-up, public health nursing supervision, and all forms of community assistance toward control. Current data relating to the patient are secured from clinics, tuberculosis hospitals and private physicians, from which each district officer is able to make periodic appraisals of the tuberculosis problem either in his entire district or in any of the counties within the district.

Time does not permit a detailed review of the many other advantages of having this information readily and constantly available. Obviously the district officer is thereby enabled to direct more intelligently the field activities in tuberculosis control, to use the data in promoting advances in case-finding methods, to secure additional clinic sessions and to employ the necessary number of public health nurses. Such data are most essential in directing the local public health nursing service along the most productive channels of service.

The case-finding activities in upstate New York are closely integrated in practically all localities with the thirty-one local tuberculosis hospitals and sanatoriums. All the county tuberculosis hospitals conduct a case-finding service as an activity of their outpatient departments. Except in one or two counties in which the total area of the county is very small, each of the hospitals conducts itinerant clinics in various sections of the respective counties. Emphasis is placed on the examination of contacts and patients who may be referred by their family physicians because of symptoms referable to the chest. There are all together approximately 120 semipermanent or permanent clinics or dispensaries, in addition to a similar service which is available for the people periodically through the itinerant service. The total number of examinations conducted in these

clinics approximated 55,000 in 1937. The total number of annual clinic examinations throughout upstate New York is between 90,000 and 100,000. The total number of special beds for tuberculosis in upstate New York is 10,326 as compared with 2,716 deaths. Of these beds, 5,537 are in state and local tuberculosis hospitals and the remainder in private hospitals or other state institutions. The ratio of total beds to deaths is 3.8 and the ratio of special public beds is 2.4.

The responsibility of the state department of health, in addition to the promotion of more adequate clinic and hospital service throughout these counties, is generally supervisory. Each hospital is surveyed annually by a representative of the Division of Tuberculosis. Specific recommendations are made regarding the scope and extent of the hospital service, and in many instances these recommendations are followed up by our district officer. In two or three of our larger cities the clinics are conducted by the local department of health, with varying degrees of participation and integration with the personnel of the local county tuberculosis hospitals.

WORK OF TUBERCULOSIS HOSPITALS

In 1930 the State Health Commission, following an intimate study of the tuberculosis control problem in New York State, recommended that the state construct three new tuberculosis hospitals and add an infirmary to Ray Brook, the one state tuberculosis hospital then existing, in order to provide hospital and other control facilities not then available in twenty-five counties.

All these counties are essentially rural and so located as to constitute four comparable districts or areas, each comprising from seven to nine counties having approximately the same population (about 300,000) and relatively the same death rate.

Each of these hospitals has been constructed in the population center of the area served. Each acts as the hub of the wheel of tuberculosis control. A continuity of medical service from case finding through treatment and follow-up of both patient and family prevails in each hospital. Tuberculosis is approached on a family and community basis, while the patient is treated as an individual.

Prior to the opening of these hospitals, the Division of Tuberculosis had for fifteen years conducted a consultation clinic service once or twice a year in the counties included in these hospital areas. As a result of this service we have been able to develop an integrated service with the general practice of medicine in these areas. The fact that practically 100 per cent of the general practitioners participate and cooperate by having their patients examined and studied by the hospital staffs has contributed more to the success of these hospital programs than any other single factor.

Each state hospital conducts an active consultation type of outpatient service within the hospital and through clinics held throughout each county in the area. Patients are admitted by a request card signed either by their family physician or by the local health officer. All patients are referred back to their physicians for a report of the examination, which is completed in detail and mailed to the referring physician. Copies of these reports are sent to the district state health officer and the local public health nurse for assistance in follow-up work.

In this clinic service, emphasis is placed on the history of contact with a known case of tuberculosis. Patients

who have experienced such contact, as well as patients who are referred by their family physicians because of suggestive symptoms or physical signs, comprise the patient attendance.

These hospitals have been in operation for approximately three years, and during the past two full years of clinic administration a total of 21,804 individuals, comprising 1.8 per cent of the total hospital areas' population, have been examined. The yield in newly discovered cases of tuberculosis among these patients was 3.1 per cent. About 50 per cent of the patients were examined because of history of contact. Of real significance is the fact that, of those patients found with tuberculosis because of the history of contact, 67 per cent were in the minimal stage of their disease, in contrast to 40 per cent of those who presented themselves to the clinic because of symptoms.

Patients are admitted for special study or treatment by applying through their family physician or health officer or directly to the superintendent of the hospital.

Following admission to the hospital, the superintendent, if he decides that the patient is unable to pay for his care, sends a bill to the clerk of the board of supervisors of the county from which the patient was admitted. Following admission, and monthly thereafter, the referring physician receives a report of the clinical progress and treatment afforded each of his patients.

Each hospital maintains a more detailed register than that of the district office. All families in which tuberculosis may be a problem are indexed in detail as to their status regarding infection, chest roentgenogram, contact with sputum positive case, clinical status, and other social and epidemiologic data.

Complete medical and surgical facilities are available in each hospital. All nurses are registered and all physicians are employed full time. A full time thoracic surgeon has been performing the major operations during alternate visits to the three hospitals, although each hospital has a resident surgeon. As a result of the advances and growth of this service which have been realized during the three years since these hospitals were opened, another full time thoracic surgeon will be engaged July 1, 1939, when the new infirmary building at Ray Brook will be opened.

The care and treatment of orthopedic patients are directed by the physicians in our Division of Orthopedics by periodic visits to each hospital.

Research and teaching characterize all phases of the program in each hospital. For many years, medical students have had the benefit of residence teaching at Ray Brook and this service, together with affiliation with schools of nursing teaching programs, is continuously carried on in the three new hospitals.

Standard nomenclature and complete outpatient and medical records are maintained in a manner by which periodic objective appraisals are made of routine practices, special circumstances or conditions relating to epidemiologic, clinical, pathologic, therapeutic or social manifestations or influences which are related to the disease.

Although the laboratory in each hospital conducts all routine examinations, each one is carrying on studies in different fields of research—in one bacteriology, in a second physiology of respiration, in a third special studies relating to the tissue reaction to the tubercle bacillus, and in the fourth pathology. In this manner

duplication of work is avoided and the special resources of all four hospitals are available to any one of the laboratories.

Occupational therapy and some vocational training and guidance are carried on in each hospital. In like manner a medical social worker in each assists the patient and family in adjusting the many industrial, economic and household problems which arise as a result of the disease.

SPECIAL STUDIES

Among the special studies which are being carried on by the Division of Tuberculosis, in addition to this routine program, are those concerned with both the epidemiology and the pathogenesis of the disease.

With special reference to case finding, the department has never looked with favor on the tuberculin testing of school children as a profitable method of finding new cases of tuberculosis. It is our conviction that the most productive method is the examination of contacts and of patients referred by physicians. Although these groups constitute a major problem in every community, there is need for case finding also in other groups, especially among adults. The examination of school children is the least productive method of finding new cases.

As a preliminary to an investigation of the epidemiology and pathogenesis of tuberculosis, selected groups of the population in several sections of the state are being examined. Some of these studies are being conducted entirely by the Division of Tuberculosis, while others are in cooperation with other state departments.

In cooperation with the Division of Industrial Hygiene of the State Department of Labor, an x-ray study of workers in various industries is being carried on. To date we have examined approximately 8,500 workers in heavy industries, including nearly 5,000 workers in foundries and some workers in grain elevators, woodworking establishments and scouring powder and asbestos products factories. The average yield of significant pulmonary tuberculosis was 1 per cent. The detailed results of these continuing studies will be published from time to time.

For purposes of public health education, case finding and investigation in pathogenesis, we have been making tuberculin tests of students and roentgenographing the positive reactors in nine teachers colleges in upstate New York. To date, 6,021 have been examined, of whom 30 per cent reacted to tuberculin and seventeen, or a percentage of 0.3, cases of reinfection type tuberculosis have been found. All negative reactors are retested during the second and third years of their attendance, and those who react, plus the positive reactors of the previous years, are roentgenographed. The details of this study will be reported at a later date.

The high incidence of tuberculosis among mental patients is indicated by the tuberculosis death rates in the New York State mental hygiene hospitals, which varied during 1937 from 200 per hundred thousand to as high as 1,700 per hundred thousand, with a rate of 812 for the total group. It should be mentioned that other death rates indicate that feeble-minded and mental patients are constitutionally inferior to the general population. The pneumonia rate, as an example, is approximately ten times greater among mental patients than among the general population; the general death rate among mental patients is 65 per thousand, whereas the rate in the entire population is 13 per thousand. From an epidemiologic standpoint this indicates that the

serious problem resulting therefrom is not limited to the spread of this disease among patients but is of extreme importance from the standpoint of the employees. The careless manner in which mental patients cough and expectorate presents problems in prophylaxis which demand special consideration and study. In like manner a study is now being conducted in one of the hospitals for the insane.¹ To date 1,295 patients have been examined, with a yield of 106 newly discovered cases of active pulmonary tuberculosis and an additional eighty whose chest roentgenograms indicate the need for further study before they can be accurately defined. The total number of employees in the institution in which this study is being conducted is 750, of whom fourteen have been admitted to the neighboring state tuberculosis hospital for treatment within the past two years. Of the 160 employees already roentgenographed, four definite cases of pulmonary tuberculosis have been diagnosed and, in addition, two other employees' roentgenograms indicated the necessity for further study before an accurate diagnosis can be made. These are in addition to the fourteen who were already hospitalized, which indicates the seriousness of this problem.

Another study which is being conducted in cooperation with this department is a continuing appraisal of the epidemiology and pathogenesis of tuberculosis by the tuberculin testing and roentgenographing of 2,300 inmates of a school for the feeble-minded. In the original examination of this group, 61 per cent reacted to tuberculin and 2.7 per cent showed x-ray evidence of reinfection type tuberculosis. All of these persons are given tuberculin tests and the reactors roentgenographed every six months. Detailed observations are made regarding their domiciliary and hospital environment, with particular reference to the possibility of contact with a person having pulmonary tuberculosis. From the standpoint of contact, the environment in which these patients are cared for is under control in that all persons with whom the inmates come in contact in the daily institutional routine are roentgenographed periodically. The results of this interesting and valuable study will be reported later.

A similar tuberculin-testing and x-ray study is being made of 500 inmates of a state institution for delinquent girls between the ages of 12 and 17 years. Constitutionally and biologically, these girls are different from those found in the feeble-minded group. Constitutionally, the latter group is more comparable to the general population than the mental patients.

In order to create more interest among physicians and general hospital authorities regarding tuberculosis, and perhaps to determine a possible cause for the apparently large numbers of nurses and interns who develop pulmonary tuberculosis, an x-ray survey of 5,000 adult admissions to fourteen general hospitals has been conducted with the cooperation of the administrators and x-ray departments of the hospitals. This study, which will be reported in detail later, revealed that 1.2 per cent of all adult admissions (excluding all known cases of tuberculosis) have pulmonary tuberculosis. In 0.5 per cent the histories contained data which might have resulted in a diagnosis of tuberculosis before the patient was discharged; in 0.7 per cent the records contained no evidence that tuberculosis was suspected. If the same conditions prevail throughout

1. The results of this study, when completed, will be published by Dr. John K. Deegan, Superintendent, Hermann M. Biggs Memorial Hospital, Ithaca, N. Y., under whose direction it is being made.

the United States, about 45,000 cases of unrecognized pulmonary tuberculosis were admitted to general hospitals last year.

As a preliminary study of workers engaged in handling foods, all the employees (1,500 in number) of a food production plant were roentgenographed. Only two cases of pulmonary tuberculosis were discovered. It is of interest that this plant is located in a county having a tuberculosis death rate of 44 per hundred thousand of population.

ECONOMIC ASPECT

In the control of tuberculosis, excluding the tubercle bacillus itself, the greatest common denominator in the problem is the almighty dollar. Although the association of tuberculosis and poverty is generally recognized, actual studies made in our service revealed some startling facts. One study of 226 consecutive patients showed that 112 were the principal wage earners of their families and 114 were dependents. Of the families in which the principal wage earner was the patient, the total family annual income exceeded \$2,500 in only six instances. Of these, two had three dependents, one had five dependents, two had two dependents and the sixth had no dependents. Since the earnings of the principal wage earner of this group were terminated at the time of illness, the economic factor assumes paramount importance. Only eight of the families of the 114 who were dependents had a family income of \$2,500 or more. The average number of other dependents was four.

Another study of 302 patients revealed that the average duration of their disease at the time the study was made was three years and four months. Of this group, all persons who had an income of \$500 or less the last year of employment were classified as dependents.

The cost of the disease, including loss of wages, physicians' services, drugs, clinic service and hospital care—whether paid by the family, locality or state—was \$5,421 for the male wage earners and \$5,132 for the female wage earners. The disease cost for the dependents averaged \$2,402.

On the other side of the family ledgers, the total annual family income was \$2,500 or more in but 3 per cent of this total group.

The economic aspect of the problem stands out in bold relief when it is realized that a survey shows that in public tuberculosis hospitals in New York State only 4 per cent of the cost of the care of patients came from the patients or members of their families. Moreover, the experience of tuberculosis hospitals throughout the United States has revealed, in a recent survey by the American Medical Association, that only 9 per cent of all patients are able to pay for part of their care and 6 per cent for all of their care.

In addition to the foregoing, other special studies—either as a part of routine administrative procedures or as special projects—are being conducted regarding such detailed aspects of the control problem as circumstances influencing the reporting of cases of tuberculosis by private physicians, the longevity of tuberculous patients following the onset of symptoms or the diagnosis, the relative value of the various methods of treatment including collapse therapy, the significance of industrial and economic factors and their effect on the patient, the family and the community, the appraisal of various routine administrative methods used in clinics, dispensaries and tuberculosis hospitals, and the deter-

mination of significant and helpful factors favoring the rehabilitation of patients and their reestablishment as self-sustaining persons in the community.

SUMMARY

To spread tuberculosis a human being must have an open lesion. The epidemiology and the study of the control of tuberculosis present a more complex problem than almost any other of the communicable diseases for which the cause is known. The transmission of infection occurs most frequently among persons in more intimate contact with the patient who has the disease. Of all persons who become infected with the tubercle bacillus, only a small percentage develop the reinfection type of tuberculosis. Pulmonary tuberculosis is a disease primarily of adults. Environmental factors seem to have a more common influence on the development of disease than do the constitutional factors. The common denominator found in the tuberculosis problem is the almighty dollar. A vicious circle prevails between poverty and tuberculosis and tuberculosis and poverty. Before many specific factors can be individually evaluated, more information must be obtained. If, however, our present knowledge could be applied to our present and future medical and public health practices, the mass behavior of tuberculosis should be changed. The tremendous amount of needless suffering, unnecessary deaths and the enormous economic losses resulting from the disease can be appreciably reduced. They should be.

ABSTRACT OF DISCUSSION

DR. LEVERETT D. BRISTOL, New York: I was impressed by the results that have been accomplished in New York State. The reduction in the death rate over the past years from 161 per hundred thousand to 44 per hundred thousand, the fact that there are now 3.4 beds per annual death in the state of New York, and that they are finding a high percentage of cases of tuberculosis in the minimal stages are all measurable criteria of progress in that state. There is no state in the United States where there is better organization for the control of tuberculosis than in New York State, including a complete coordination of effort between local groups, county agencies, the district groups of the state department of health and the strong voluntary tuberculosis and public health committees which exist. Also, the leadership of the state department of health, through Dr. Plunkett's division, has had a great deal to do with the results accomplished. It has conceived its function not only to be one of routine service to the people of the state but also to carry on educational phases and particularly research studies. If I were to emphasize anything as to tuberculosis in industry it would be that the great majority of people are employed by smaller industries, in groups where they do not have facilities for careful examinations of applicants, periodic health examinations or tuberculosis case finding. More and more the public agency interested in tuberculosis must come to the assistance of these people and work out a cooperative program with the smaller private industries. I hope that Dr. Rice will tell us of the work that the New York City Department of Health has been doing in cooperation with some of the industrial organizations in tuberculosis case finding. In only a few of the larger industries are employees paid when they are away from their job on account of sickness. If we are to get at the economic problem of tuberculosis, it must be possible for employees in the smaller industries to be remunerated when they are away taking the cure. Dr. Plunkett has raised a question with reference to tuberculin testing of school children. He represents the official agency which has to think in terms of profitable investment of tax money. When Dr. Plunkett suggests that his own department sees little value in tuberculin testing of children, I may agree with him so long as the reference is particularly to grade school children; but with reference to high schools and college

groups it is certainly worth continuing this important work. I shall look forward to the continuation of Dr. Plunkett's studies in New York State.

DR. EARL MORRIS, Hays, Kan.: As a student health director, I should like to ask two questions: First, shall I continue to give tuberculin tests in my program of case finding or should I disregard it as quite largely a waste of time and money and center on the x-ray film and fluoroscope, and perhaps a more intensive examination of the family and other contact history? Second, if I continue tuberculin testing, as I probably shall, in my program—we require hygiene of all freshmen, and as we come to the section on tuberculosis we do tuberculin testing as a routine class procedure, a piece of laboratory work . . . should there be any difference in advice given to negative and positive reactors; in other words, may my students regard the results of tuberculin tests as contributing something to their future program of personal and community hygiene?

DR. JOHN L. RICE, New York: For the past few years, Dr. Edwards, who is the director of the Bureau of Tuberculosis, has been carrying on an extensive case-finding program among special groups in New York City. Examples of such groups are 75,000 adults receiving home relief, about 7,000 persons in a district inhabited largely by Puerto Ricans, about 5,000 pupils in the city's high schools, and several thousand patients attending the venereal disease clinics. Altogether about 150,000 adults and young adults have been surveyed by means of paper-film x-ray examinations, and this has disclosed about 3,500 new cases of tuberculosis. It has been gratifying that in a large proportion of these cases the disease was in its early stages. Dr. Edwards is now extending this case-finding project into the industrial field—beginning with those engaged in the fur industry. This particular survey is being made at the request of the industry.

DR. ROBERT E. PLUNKETT, Albany, N. Y.: From the standpoint of the epidemiology of tuberculosis, it must not be forgotten that tuberculosis is constantly becoming a disease of older persons and that this applies particularly to males. In 1915 in upstate New York the highest death rate in males from tuberculosis was in men between the ages of 25 and 35 years. In 1937 the peak was in the group between 55 and 64. This is quite a change over a period of twenty-two years. In eleven years in upstate New York, the average ages of patients both whose cases are reported and who died have increased by five years in males and by three years in females. This change is considerably greater than the increase in the average age of the population during the same period. In our clinic service, on the basis of two years' experience, it costs us—and it is a selected group of the population, made up of persons referred because of contact or suspicious symptoms—\$1,737 to discover a case in a child under 15 years, \$77 to discover a case in a person over 45, and \$119 for all over 15 years of age. Dr. Morris wanted to know whether he should still use the tuberculin test. There is a definite place in this field for the tuberculin test, but before using it there should be intelligent consideration of the size and scope of the problem. If he is working in a community with a death rate of 20 or 30, he will save money by doing the tuberculin test, but if he is studying adults in a community with a death rate of 60 or 70, he will waste time and money by doing tuberculin tests. Although tuberculin still has a place, the x-ray examination is in general more useful in finding tuberculosis and is useful also in discovering other pathologic conditions in the thorax. We are using tuberculin in our normal school studies and other studies, but the thing we are opposed to in New York State is the program, which has been so popular for seven or eight years, of using the tuberculin test as the basis of case finding among school children and of stopping there. There is too little attention given to the home in which that child lives and to the economic and domiciliary factors which influence the spread of tuberculosis within the family. If a child reacts to tuberculin, the younger the child the more likely it is that the infection occurred in the home. As the child grows older, the more likelihood there is of infection outside the home. The home should be searched to make sure that the cause is not there. As far as the negative reactors are concerned, they might be followed to see how soon they become positive, and some day there may be data concerning the development of positive reactors which will be of primary significance.

RESULTS OF TREATMENT IN A PSYCHIATRIC OUTPATIENT DEPARTMENT

A FOLLOW-UP STUDY OF 166 CASES

HUGH T. CARMICHAEL, M.D.

AND

JULES H. MASSERMAN, M.D.

WITH THE ASSISTANCE OF CHARLOTTE G. BABCOCK, M.D.
CHICAGO

In this paper we present the observations made in a follow-up study of 166 patients who had been treated in the psychiatric outpatient department of the University of Chicago Clinics between July 1, 1935, and March 30, 1937. We have attempted, by means of a review of the records and follow-up interviews, to evaluate the results of treatment, to compare the original diagnoses with the diagnoses made at the time of the follow-up interviews and to relate the present study with a previous study on inpatients.¹

METHODS AND MATERIALS

The criteria for inclusion of a patient in this study were that he had been seen originally by one of us at least one year previously to the time of follow-up and that a thorough physical and psychiatric work-up had been recorded when the patient was first seen.

Of the 206 cases reviewed, forty were discarded for the following reasons: Eighteen patients had also been inpatients and had received more intensive treatment than the others; in sixteen instances the data recorded at the time of the original interview were too few to permit conclusions to be drawn, and six patients could not be reached.

The time between the first visit of a patient to the clinic and the follow-up study ranged from one year to two and one-half years. The time in months since the patient's last visit to the clinic ranged from one to thirty. These wide ranges are explained when it is realized that a number of patients were seen on only one occasion, while others continued to make visits to the outpatient department over as long a period as eighteen months.

The sources of referral of patients were as follows: Ninety-seven were referred from other departments in the University of Chicago Clinics. Twenty-nine had been sent by their families or by friends. Twenty-four came of their own initiative. Nine were referred by outside physicians and seven by social agencies.

It will be of some interest to consider briefly certain of the statistical data shown in table 1. The 166 cases are distributed through fifteen diagnostic categories. The diagnostic criteria used in assigning cases to the various categories are those set forth by the American Psychiatric Association and the National Committee for Mental Hygiene in 1934.² The series is composed of 115 cases of neurosis, thirty-one of psychosis, nineteen of psychopathic personality and one of epilepsy. The

individual diagnostic groups contain few cases, with the exception of anxiety state with twenty-nine cases, mixed psychoneurosis with forty-one cases, psychopathic personality with nineteen cases, conversion hysteria with seventeen cases, and manic-depressive psychosis with thirteen cases (all instances of depression).

Eighty of the 166 patients were male and eighty-six were female. The mean age of the group was 30.1 years. The average school grade attained by the 127 patients concerning whom information as to education was available was 10.2. Forty patients were foreign born, fifty-five were born in the United States of foreign-born parents and seventy-one were born in this country of parents who themselves had been born here. Sixty-nine patients were single, eighty-six married, four separated, five divorced and two widowed. Seventy-seven patients gave their religious affiliations as Protestant, forty-eight professed to be Roman Catholic, thirty-two were of Jewish faith and nine indicated no religious affiliations or said they had no religion.

The 100 cases were distributed throughout fifteen diagnostic groups, but only three groups contained more than ten cases, viz., anxiety state with twenty cases, mixed psychoneurosis with nineteen and conversion hysteria with eleven (table 2). Evidence of organic disease had been found in thirty-four of the 100 patients at the time of the original physical examination³ (table 2).

RESULTS AND COMMENT

In table 2 are shown the differential symptoms in the 100 followed-up cases. Perusal of this table shows that disturbances of both somatic and mental functions were complained of by patients in all diagnostic groups. Complaints of somatic dysfunction were not confined to any one of the organ systems or sensory modalities. Likewise, disturbances of mental functions are seen to occur in all diagnostic groups, with the exceptions that delusions and hallucinations are not found among the psychoneuroses or psychopathic personalities.⁴ These figures seem to indicate that most neurotic and psychotic reactions tend to be of mixed character.

The question of the relation of the somatic symptoms of neurotic and psychotic patients to the various organic systems of the body is one of great interest. Careful study showed that frequently a patient had no complaints referable to an organ system in which disease

existed. For example, a patient who showed evidence of rheumatic heart disease made no complaints regarding the cardiovascular system but had numerous complaints of dysfunction in several of the other systems. On the other hand, patients with somatic complaints in whom no definite evidence of organic disease was found at the initial examination later showed positive signs of organic disease related to the original somatic complaints.

There is also, of course, the puzzling question of why the individual patient chooses the particular organic system or systems to which he refers his complaints. Fenichel,⁵ in discussing this problem in relation to the field of the so-called organ neuroses, pointed out that some of the multiple determining factors are: "somatic compliance, special factors in the infantile history of the individual, a partial pregenital fixation, and the particular suitability of an organ for symbolic representation." Similarly, the tendency shown by patients to shift their somatic complaints from one system to another or to add complaints referable to another system was exemplified strikingly in our series of patients.

Our present study demonstrates clearly that a neurosis and organic disease may be present in the same patient, that a neurosis may precede or follow the development of organic disease, and that a neurosis or psychosis may mask the presence of organic disease or that the reverse of this may occur. Our observations in a previous study¹ with reference to symptoms were the same as those reported here. Comroe,⁶ in a follow-up study of 100 cases of "neurosis," reached conclusions which are essentially in agreement with those we have just expressed, and he emphasized forcibly the necessity for thorough examination of neurotic patients so that the presence of organic disease will not be missed.

In our investigation of etiologic factors there were noted certain trends, which may be presented at this point. Ingestion of alcohol appeared to be a factor in six cases and the use of barbiturates in one case. Somatic disease was present in thirty-four of the 100 cases but did not play a direct etiologic role in all instances. Five patients were found to have varying degrees of mental deficiency.

Entirely apart from the deficiencies in the records, it was found most difficult to evaluate the psychologic factors concerned in the etiology, inasmuch as the importance attached to the various maladjustments shown by the patients depended on the reliability of the sources of information, the thoroughness of the psychiatric examination, and the training and personal bias of the psychiatrist who had obtained and interpreted the data. As might be expected, environmental difficulties of familial, economic, occupational, marital, religious, social or sexual nature were found to be factors. Usually the difficulties were present in more than one environmental sphere and in most cases these exogenous factors were combined with endogenous personality difficulties in producing symptoms.

When we endeavored to classify the patients as to the personality they presented before the onset of the neurosis or psychosis, we immediately encountered almost insuperable difficulties inherent in any attempt to group patients under various personality types or to ascertain what earlier sets of traits and attitudes can be correlated with the clinical pictures presented in the

3. Ten of the twenty patients with anxiety states had various organic diseases, viz., one case each of rheumatic heart disease, auricular fibrillation, central nervous system arteriosclerosis, hyperthyroidism, strabismus, multiple sclerosis, menopause and chronic cholecystitis and two cases of essential hypertension. Among those with conversion hysterics the following organic conditions were present: one case each of thrombosis of the right subclavian vein, essential hypertension, hypothyroidism following a previous thyroidectomy and chronic prostatitis. Four of the patients with manic-depressive depressions showed physical abnormalities, viz., two cases of uterine fibromyomas and one case each of traumatic atrophy of the left upper arm and acute gonorrheal urethritis. In the group of mixed psychoneuroses, six patients were found to have physical diseases, viz., one case each of osteomyelitis, rheumatic heart disease with nodular goiter and elevated basal metabolic rate, and uterine fibromyomas with secondary anemia. In both the group of behavior disorders and that of reactive depression a case of chronic epidemic encephalitis was included. The group of cases of psychosis with disease of the central nervous system was made up of one case of presenile psychosis, one case of tabetic dementia paralytica and one case of arteriosclerosis of the central nervous system. Two of the patients with psychopathic personality were found to have syphilis. Perhaps two other cases, which are not recorded in table 2, should be considered to present evidence of organic disease, viz., one patient with reactive depression had hemorrhoids with severe secondary anemia, while the patient with undiagnosed psychosis had obesity.

4. Attention may be drawn to the large number of cases in which complaints referable to the muscular system (sixty-seven cases) and to the gastrointestinal system (fifty-three cases) were made. Complaints referable to the sexual function (which included impotence, frigidity, ejaculation praecox and masturbation) were made by thirty-seven patients. Among disturbances of mental functions, anxiety (seventy-four cases) and depression (fifty-three cases) were the most commonly observed symptoms. Phobias were noted in twenty-nine cases.

various psychoses and neuroses. An excellent example of this is shown in the report by Bowman and Raymond⁸ on studies of the prepsychotic personality in schizophrenic patients and in Bowman's⁹ study of the personality in schizophrenia, affective disorders and dementia paralytica and in normal subjects. Among the difficulties encountered is the confusion which obtains at times as to whether certain traits are prepsychotic characteristics or early psychotic manifestations. A second difficulty is that of estimating the reliability of the information given. With only one informant it seems easy to code the personality traits of a patient, but when there are several informants, the number of traits put down as unknown or questionable increases markedly. Other considerations concern changes in diagnosis and the difficulty of having too many persons collect and evaluate the data.

The great importance of studies of the prepsychoneurotic personality has been stressed by Hinsie.¹⁰ He

information was available there seemed to be so great a mixture of traits and attitudes that it was found impossible to fit the patients into such categories. One word characterizations of personality, such as "perfectionistic," "aggressive" and "normal," were discarded, since they seemed woefully inadequate when used to describe a complex structure such as the human personality.

In our previous study of inpatients¹ we tried to estimate the degree of insight manifested by the patients and drew up definitions of various grades of insight. It has always been a difficult question to decide how much insight a patient has. Indeed, it is a moot question as to whether satisfactory criteria can be set up. In table XI of our previous paper¹ the following definitions of five degrees of insight are given:

[The patient] (1) does not consciously admit psychogenesis of illness but instinctively keeps returning to psychiatrist for aid; (2) admits psychic nature of illness but constructs vague

pointed out that a knowledge of the personality previous to the onset of neurosis is missing in the psychiatric literature, whereas the term "prepsychotic personality" is in the everyday language of the psychiatrist. This reminds us of an additional difficulty in studies of personality in neuroses and psychoses, namely, the lack of studies on so-called normal controls. Bowman⁹ referred to this as a valid criticism and attempted to meet this objection by studying a group of normal controls for personality traits.

We were not satisfied with the results of our efforts to classify the 100 followed-up cases under various personality "types." It was possible to classify some patients by such a term as "schizoid," "cyclothymic" or "shut-in." In the majority of cases in which adequate

rationalizations as to "nerve strain from overwork," "nervous breakdown," etc.; (3) admits the relationship of emotional difficulties to his illness but insight mainly intellectual, and tendency to blame others for inner conflicts persists; (4) realization of the significance and personal origin of his past emotional conflicts but rejection of insight that would occasion severe narcissistic trauma; (5) deeper insight into ambivalence and inner conflicts, including those arising from erotic urges and unjustified aggressive drives previously repressed.

The definition of the fourth degree might be said to be the point at which real insight begins, while what is defined as the fifth degree constitutes a close approximation to the self understanding that is the goal of all psychotherapists for their patients but which probably is not readily attainable by other means than psychoanalysis. The facts and comments just noted, together with the inadequacy of our records, seem to preclude any conclusions regarding the degree of insight in the present series of patients.

As in our previous study of inpatients,¹ we wished to examine the prognosis assigned to patients and to

compare it with their actual status at the time of follow-up. On the basis of the information in the case records, we could estimate prognosis in only three degrees, namely, that the patient was expected to get worse, to show no change or to show improvement. On this basis we estimated that thirty-one of the 100 patients would remain in statu quo or get worse and that sixty-nine would show varying degrees of improvement. As far as the information was available, we tried to determine prognosis from several interrelated considerations.¹¹ On comparison of the results at the time

An attempt to evaluate the effectiveness of any single therapeutic method could not be successfully carried out, since more than one method was used in almost all cases. The methods of treatment employed include all indicated medical and surgical measures, sedation, environmental readjustments, interviews with psychiatric social workers, and superficial psychotherapy such as reassurance, suggestion and persuasion. Institutional care was recommended for some of the psychotic patients. In three cases a formal psychoanalysis was advised. Owing to the small number of cases in the

Code: Change in Symptoms		General Status	
Worse (col. 2 and 0)	Symptoms worse (—1 to —5).	Died (col. 16)	Death
No change (col. 3 and 10)	Symptoms unchanged.	Institutionalization (col. 17)	In public or private mental hospital.
+1 (col. 4 and 11)	Slight or intermittent symptomatic improvement.	Worse (col. 18)	General status worse (—1 to —5).
+2 (col. 5 and 12)	Greater improvement but extent variable, with tendency to form other symptoms.	No change (col. 19)	Remains in statu quo.
+3 (col. 6 and 13)	More stable improvement with recurrence of symptoms only under stress.	+1 (col. 20)	Slight and variable improvement in somatic complaints, mental symptoms or environmental difficulties.
+4 (col. 7 and 14)	Disappearance of presenting symptoms with a residuum of only a few minor complaints.	+2 (col. 21)	Definite improvement in one or more of these spheres, but some complaints still present and general adjustment at a somewhat lower level than previous to onset of the patient's illness.
+5 (col. 8 and 15)	Complete disappearance of symptoms, with no return under severe emotional and environmental stresses.	+3 (col. 22)	Recovery from presenting symptoms with satisfactory resumption of occupational, familial and other duties unless subjected to severe stress.
		+4 (col. 23)	Complete recovery from presenting symptoms with apparent capacity to maintain this even under severe stress.
		+5 (col. 24)	Complete and stable recovery with marked improvement in capacity for personal and social adaptations.

Code: Change in Symptoms

- Worse (col. 2 and 9) Symptoms worse (—1 to —5).
 No change (col. 3 and 10) Symptoms unchanged.
 +1 (col. 4 and 11) Slight or intermittent symptomatic improvement.
 +2 (col. 5 and 12) Greater improvement but extent variable, with tendency to form other symptoms.
 +3 (col. 6 and 13) More stable improvement with recurrence of symptoms only under stress.
 +4 (col. 7 and 14) Disappearance of presenting symptoms with a residuum of only a few minor complaints.
 +5 (col. 8 and 15) Complete disappearance of symptoms, with no return under severe emotional and environmental stresses.

General Status

- Died (col. 16) Death.
 Institutionalization (col. 17) In public or private mental hospital.
 Worse (col. 18) General status worse (—1 to —5).
 No change (col. 19) Remains in statu quo.
 +1 (col. 20) Slight and variable improvement in somatic complaints, mental symptoms or environmental difficulties.
 +2 (col. 21) Definite improvement in one or more of these spheres, but some complaints still present and general adjustment at a somewhat lower level than previous to onset of the patient's illness.
 +3 (col. 22) Recovery from presenting symptoms with satisfactory resumption of occupational, familial and other duties unless subjected to severe stress.
 +4 (col. 23) Complete recovery from presenting symptoms with apparent capacity to maintain this even under severe stress.
 +5 (col. 24) Complete and stable recovery with marked improvement in capacity for personal and social adaptations.

of follow-up examination with the prognosis as previously estimated, it was found that we were correct in eighty-seven cases. However, this figure cannot be accepted at face value, since under the heading "improvement" we had included all degrees up to complete recovery.

In table 3 are shown the degrees of change in somatic and mental symptoms and an estimate of the general status of the patients who were observed at the time the follow-up study was made. These were graded on the basis of the definitions set forth at the bottom of the table.

11. Criteria for determination of prognosis were (a) an evaluation of the patient's constitutional makeup, both physical and mental; (b) the nature and intensity of previous neurotic or psychotic reactions; (c) the type, duration and severity of the presenting illness and the depth of emotional reactions, and (d) the results of the various forms of therapy which had been used previously, including the availability of an extramural milieu devoid of occupational, familial, social, economic or sexual stresses beyond the capacity of the patient to withstand (see our previous paper on inpatients¹).

individual diagnostic groups, no conclusions of statistical significance can be drawn regarding the results in any one diagnostic category.

A study of table 3 reveals the following facts: One death and one suicide occurred in our series. Three patients were psychotic with disease of the central nervous system. Thirteen patients had received institutional care, though several had been discharged previously to the time of the follow-up study. Of forty-nine patients who showed little or no improvement, sixteen were worse, fourteen had shown no change and nineteen showed very slight improvement. Fifty-one patients showed a degree of improvement graded plus 2 or better. Those who showed a degree of improvement of plus 3 or better numbered thirty-six. Only two patients were considered to show complete and stable recovery, although fourteen other patients gave evidence of apparent recovery.

Inspection of the results attained in the seventy cases of neurosis, the twenty cases of psychosis and the nine of psychopathic personality reveals that improvement of plus 2 or better was shown by thirty-nine neurotic patients, seven psychotic patients and four subjects with psychopathic personalities.

At the follow-up study it was found that in the interval since the last visit six patients had developed complaints which could be attributed to toxic or organic factors which had not been apparent at the time of the original physical examination. In three of the cases the original symptoms might, in retrospect, be considered as having pointed to the possibility of organic disease. In the three remaining cases the organic changes appeared to be entirely new developments (table 4).

The figures on improvement rates agree fairly closely with those reported by us for inpatients.¹ In the inpatient study, fifty-four patients showed 2 plus improvement and thirty-eight patients showed 3 plus

The difficulties of evaluating the effects of therapy in neuroses and psychoses, particularly psychotherapy, are enormous. In the first place, standard criteria of recovery are lacking. There is a tendency to use terms such as "improved," "recovered" and "well" without any attempt at definition. The same terms are used by different authors to denote varying degrees of improvement. To utilize the disappearance of the outspoken symptoms as a sign of cure is, as a rule, not justifiable. What appears to be improvement early in the course of treatment may be simply the result of the confidence the patient has developed in the physician. When this "transference" is disturbed, the patient's symptoms may all recur. The method by which the follow-up data are obtained is another important consideration. As Romano and Ebaugh¹⁷ pointed out, "it is not possible to speak of cure, remission, partial recovery or improvement on the basis of statements made by the family, friends or even patients." They also emphasized the defects of prognostic studies when the social investiga-

improvement. Skottowe and Lockwood,¹² in a study of the fate of 150 psychiatric outpatients, found that about 35 per cent were "recovered" or "much improved," whereas 65 per cent achieved only slight or moderate improvement. Yaskin¹³ reported recovery in forty-one and improvement in forty-one of one hundred patients with neurosis. Ross¹⁴ reported 45 per cent of 1,186 patients as well and 25 per cent as improved one year after discharge. Three years after discharge the figures for 421 patients were 40 per cent well and 10 per cent improved. After five years 34 per cent of 290 patients were well and 6 per cent improved. Luff and Garrod¹⁵ reported that 65 per cent of 500 patients were improved or much improved on discharge and that 55 per cent showed these degrees of improvement at follow-up examination three years later. Landis¹⁶ gave the number of patients discharged annually as recovered or improved per hundred admitted to state mental hospitals in the United States from 1926 to 1933 as forty.

tion and questionnaire methods were used, and the necessity for a personal interview with the patient by the psychiatrist. The Five Year Report (1932-1937) of the Chicago Institute for Psychoanalysis¹⁸ stresses the fact that the final judgment of the results of treatment must rest mainly with the physician who carried out the treatment.

Malamud and Render¹⁹ quite properly insisted that a follow-up period of at least five years is essential to obtain reliable results in studies of the course and prognosis in schizophrenia. They found that the percentage of "complete recoveries" is much lower when follow-up study is done at least five years after discharge than it is when the study is made after a shorter period, e.g., one year. The results reported by Ross¹⁴ for the neuroses tend to confirm this opinion.

A serious handicap in the evaluation of the results of psychotherapy is that all too frequently the actual therapeutic measures have not been clearly defined; more

often than not they consist of a mixture of psychotherapeutic and other methods. This state of affairs has been mentioned by various authors (Curran,²⁰ Luff,²¹ Mapother²²). Another difficulty is the failure to make careful selection of patients before beginning psychotherapy (Curran²⁰). Since there tend to be a difference in the criteria of selection of patients for psychotherapy and also decided variation in the duration of treatment and in the methods employed, it is not justifiable to compare closely the results reported by the different clinics. We have previously pointed out¹ that any estimate of the effects of a therapeutic procedure must depend primarily on its aims and standards. For example, directly to compare the results in a series of patients treated as were the patients reported in the present study with the results obtained by formal psychoanalysis¹⁸ is, strictly speaking, not permissible. Full recognition must be accorded to the following facts: Our patients were probably not selected as carefully as are the patients for psychoanalysis; the treatment they received was not as intensive; our criteria for improvement (table 3) were less severe and were based to a greater degree on overt social adjustments, while the criteria used to estimate improvement of psychoanalytic patients were far more searching and exacting and based on changes of a stable nature in the inner organization of the personality.¹⁸

In table 4 are recorded the changes in diagnosis made at follow-up examination. For twenty-two patients a change in diagnosis was made. A new diagnosis was based essentially on reconsideration of the original data and of the clinical observations made during the time the patient was under treatment. In five instances the changes made had been foreshadowed by the secondary diagnosis made when the patients were originally classified.

The problem of change of diagnosis has been discussed by Bowman⁹ in his study of the prepsychotic personality and also by Bowman and Raymond⁸ in their paper on the personality of the schizophrenic patient. In the former paper Bowman pointed out that incorrect diagnosis may be a source of error in studies of the prepsychotic personality. He cited the necessity he found for reconsideration of original diagnoses made at the Boston Psychopathic Hospital in ninety-one of 241 cases in which the condition had been differently diagnosed at other state mental hospitals. In about 40 per cent of the cases he agreed with the new diagnosis. It should be remembered, however, that the patients were under observation for relatively few days at the Boston Psychopathic Hospital, while an observation period of a month or more was available at the state hospitals. It is unquestionable that the longer period of observation is an aid in correct diagnosis. Another factor which helps to explain changes in diagnosis at various hospitals is that there may be considerable differences between the hospitals in the way they apply the standard terminology in classifying patients. This whole topic has been thoroughly discussed by Wilson and Deming²⁴ in a statistical study of psychiatric diagnosis in Massachusetts State Hospitals in 1925 and 1926. These authors found that there was disagree-

ment between the diagnoses made at the Boston Psychopathic Hospital and those made at other state hospitals in 42 per cent of the cases or, if the undiagnosed cases are discarded, in 34 per cent. In our previous paper on inpatients¹ there was a change in the diagnosis made on discharge from the hospital in forty-one of the 100 cases in which the patients were rechecked at least one year after discharge.

The number of changes in diagnosis in the present study (twenty-two) is in marked disagreement with the forty-one changes of diagnosis made on inpatients.¹ This fact raises a number of questions. In the first place, it must be pointed out that there were seventy cases of psychoneuroses in the present study, while in the previous study there were only thirty-two. Moreover, a diagnosis of mixed psychoneurosis was made in nineteen cases in this study as compared with only six in the former study. Other possible factors may reside in the fact that the review of diagnosis in the present study was made in each case by the psychiatrist who originally saw the patient, as well as in the circumstance that, of the 100 patients followed up in the present study, sixty-four were seen by one of us and thirty-six by the other.

SUMMARY AND CONCLUSIONS

One hundred patients who had been studied in the psychiatric outpatient department of the University of Chicago Clinics were examined again in a follow-up interview at least one year after the time of their original visit to the clinic in an attempt to evaluate the results of treatment and to compare the original diagnoses with the diagnoses at the time of follow-up.

The main observations and conclusions are as follows:

1. Disturbances of both somatic and mental functions were complained of by patients in all diagnostic groups. Complaints of somatic dysfunction were not confined to any one of the organic systems or sensory modalities. The various disturbances of mental function occurred in all diagnostic groups, with the exception that delusions and hallucinations were not associated with the psychoneuroses or psychopathic personalities. A tendency for neurotic and psychotic reactions to be of a mixed character seems to be indicated by these observations.

2. Fifty-one of the 100 followed-up patients showed a degree of clinical improvement graded as 2 plus or better; i.e., they showed, at the minimum, definite improvement in one or more of the states listed as somatic complaints, mental symptoms or environmental difficulties, though some complaints still persisted. Thirty-six patients showed an improvement graded as 3 plus or better at the follow-up study. By "3 plus" is meant that the patient recovered from presenting symptoms with satisfactory resumption of occupational, familial and other duties unless subjected to severe stress. These figures compare favorably with the results reported by other authors and indicate the usefulness of "superficial" methods of psychotherapy in the treatment of psychiatric outpatients.

3. The necessity for careful and thorough recording of data relating to such topics as heredity, early behavior traits, personality, onset of present illness, etiology, prognosis, insight and diagnosis at the time of the original investigation of the patient's neurosis or psychosis seems readily apparent as a result of this study. In addition, the terms used in connection with all of

the topics just noted require careful definition before one embarks on any investigation of them.

4. The need of further studies of the neuroses as regards personality, the course of the illness and the results of various forms of treatment is emphasized by our experiences in this study and by the reports in the literature.

ABSTRACT OF DISCUSSION

DR. LLOYD H. ZIEGLER, Wauwatosa, Wis.: The authors are to be praised for attempting to follow psychiatric outpatients with the aim of evaluating the effects of therapy. They have been frank in emphasizing the many difficulties encountered which tend to detract from any substantial conclusions. What might have happened to an equal number of similar patients without any medical help whatever is a suggested control study which might modify their conclusions somewhat. All of us have seen a psychosis completely camouflage unrelated, serious disease of the body, and conversely we have seen a psychosis mimic serious disease of the body, much to the chagrin of physicians. The pattern that psychiatric disease assumes has embryonic roots, so to speak, in the psychobiology of the person. It is for this reason that psychobiology from a basic science standpoint is as important as histology. This means much more than detection or study of some neurotic traits of childhood. It means an appraisal of basic attributes and growth. A person develops variable degrees of stability between his external and his internal environment. The tendency to misinterpret either of these may result in a psychosis or neurosis. A psychosis and neurosis are not mutually exclusive and too much good effort has been expended in trying to establish their artificial boundaries in an arbitrary way, when in reality all important have been the subtle forces, in which cause and effect are indistinguishable, which have changed the person or rendered him disabled. We are gradually learning that words often conceal quite as much truth as they reveal. Part of the truth is as damaging as a falsehood. This seems particularly apropos in using words such as "personality types," "diagnostic nomenclature," "recovery," "prognosis," and a host of other terms. But we can in a crude way study man and animals too in some fundamental ways. Energy, activity, emotions, interests, man's facility with symbols in thought, memory or imagery—all these deserve understanding that we may know how man makes every conceivable type of adaptation, whether socially approved or not. Prognosis means to know beforehand. Experience will teach one that certain combinations of symptoms and signs usually disappear, while others do not. The criterion of being able to or having returned to accustomed occupation is a practical goal against which to evaluate prognosis in our work. Other criteria obtain, such as living outside a hospital, or return to preillness status, to be self supporting, to survive or to get along. The integrity of psychiatry will be furthered if psychiatrists give adequate attention, as the authors have done, to somatic as well as psychic aspects of personality function.

DR. WILLIAM NELSON, St. Louis: I think this paper rather illustrates the fact that we cannot classify mental illnesses accurately even after a long period of study in many instances and that, as far as present terminology is concerned, it does not answer the purpose adequately. I think also that the question of mental illness and the manifestation, as one sees it at different periods of the manifestation of it, is bound to shift in symptomatic manifestation. In other words, we shall frequently see psychoneurotic manifestations along in the course of more frankly organized mental states, and so, when it comes to a question of determining the nature of the disease from the basis of the manifestation at any one particular phase of it, it is very difficult to do. In the first place, we have multiple manifestations; in other words, we do have a mixed personality and the manifestation that occurs in the illness of the individual is going to be largely in pattern form similar to the reactions that the individual has engaged in in his normal life. I wish it were possible in my own reasoning to be able to state a justification for the work that I do. One of the most difficult things in practice is to be able to see who has improved and who has not. After all, the crucial test depends on social adjustment. Now

that is bound to be manifest in various sources and, depending on the breadth of experience of the individual, will be the possibility of evaluating his usefulness. The individual who has rather multiple relationships and does not retreat into some protected relationship is bound to be the one to whom this kind of comparison is going to apply more critically than to the individual who lives in a protected environment. The question then of evaluating treatment is largely open to dispute. I know of no way whereby the results of such treatment can be actually evaluated.

DR. WALTER FREEMAN, Washington, D. C.: I noticed in the tables that, of twenty cases of anxiety neuroses, ten were associated with some organic disease. Is this to be interpreted as a chicken-and-egg problem? Which came first, the neurosis or the organic disease? According to these statistics it would seem that the anxiety neuroses should be particularly investigated on account of the frequent concurrence of organic disease.

DR. U. G. DARLING, Chicago: The title of the paper is "Results of Treatment in a Psychiatric Outpatient Department," and the paper dealt principally with the resultant change in diagnosis. I wonder what type of treatment was used to bring about the change in certain individual cases, or is this just a report of a gradual, progressive change that came about through time and observation? I note also that it said "Relative to the associative qualities of somaticopsychic relationships due to the derangement of the autonomic system." It appears to me that many times we can arrive at an earlier diagnosis if we study carefully the autonomic reflex psychic disturbances rather than just simply analyzing the psychic.

DR. H. T. CARMICHAEL, Chicago: Dr. Ziegler raised the question as to what would have happened in a control series of cases in which no treatment was given. Of our series of 166, thirty-seven of the patients made only one visit to the clinic and received no treatment other than the psychotherapeutic effects which are inherent in any initial psychiatric interview. We compared the results in these patients with the results in patients who had made repeated visits to the clinic and found that the results were not nearly as good in the former group as in the latter. With regard to Dr. Nelson's comments, it was not our intention to imply that inadequacy of personnel led us to get these results. I do not feel that is the point at issue at all. I agree with him that we can justifiably raise questions about the adequacy of our present system of psychiatric nosology. As to Dr. Freeman's question about the twenty patients with anxiety states of whom ten showed evidences of organic disease, we were not able to decide which came first. Sometimes we felt that they coexisted; at other times we felt that one came first and the other followed, but we could not be sure and we do not feel ourselves in a position to make any flat statement in that regard. Dr. Darling is right in picking out the fact that our title emphasizes results and that we talk perhaps a little more about some other things than we talk about results. What we had in mind was to emphasize the great difficulties that are encountered by any one who attempts to make a study of results of psychiatric treatment. We did make a statement as to the various types of treatment used, but there were so many that we felt we could not evaluate any method individually. We used all the indicated medical and surgical measures and also all the superficial psychotherapeutic methods. We did not make any definite attempt to investigate the autonomic nervous system as such, but in our general investigation of these patients we took it into consideration.

Hugh Owen Thomas.—Now Hugh Owen Thomas was the son of a bone-setter who practiced in the same district of Liverpool in which his son afterwards lived and practiced. Moreover, Evan Thomas, the father, was the seventh bone-setter in lineal descent, the previous six having been farmers in Anglesey who also practiced the art of dealing with injuries. There is no doubt that they were held in high esteem, for one evening Sir Robert Jones showed me a series of cuttings from old newspapers extolling the services rendered by various generations of this family, and their virtues have been recorded in Welsh song.—Power, Sir D'Arcy: British Masters of Medicine, Baltimore, William Wood & Co., 1936.

BOTULISM: DEMONSTRATION OF
TOXIN IN BLOOD AND
TISSUES

HARRY J. SCHNEIDER, M.D.

AND

ROY FISK, Ph.D.

LOS ANGELES

The diagnosis of botulism is often difficult when the disease occurs in isolated instances. It is made largely on the history and the physical examination, confirmed whenever possible by the demonstration of the organism or toxin in the source of poisoning. In fatal cases even necropsy gives little pathognomonic evidence of this disease, although Schwarz¹ has recently called attention to certain histologic appearances in the central nervous system which he thinks may be specific of botulism. The demonstration of toxin in the blood or tissues in suspected cases, apart from the demonstration of *Clostridium botulinum*, should be of value in the diagnosis of the disease but as far as can be determined has not been successfully accomplished in this country.

It is generally believed that the amount of botulinus toxin necessary to produce symptoms in the patient is so minute as to preclude its detection in the blood. However, scattered attempts with variable results have been made in the past. Kob (1905) is quoted as having been the first to observe that botulinus toxin can be demonstrated in the patient. He succeeded in doing this with the blood of a child nine days after intoxication. Other European workers have found the toxin in the blood serum up to the twenty-fifth day. Bergman, Insulander and Lindblad² reported an outbreak of four nonfatal cases of botulism with characteristic symptoms of moderate degree. Botulinus toxin was demonstrated in the blood serum in two of these cases on the seventh day of illness and in the other two on the tenth day. Negative results were obtained, however, with the blood serum of the first two patients on the tenth day, after antitoxin (50 and 100 cc.) had been administered on the seventh day. The source of the toxin could not be demonstrated but they concluded that the poisoning was due to the ingestion of salted fish. Longo³ recently reported that the toxin was apparently demonstrated in the blood serum of a patient ill four days, by guinea pig injection.

In the American literature the only reports on this aspect of the subject have dealt with unsuccessful attempts to demonstrate the toxin in the blood of patients. Lindsay, Newman and Hall⁴ reported two fatal cases in which blood taken twenty minutes after death failed to show the presence of toxin when injected into guinea pigs in amounts of 1 cc. These investigators state that Glassman has in experimental animals demonstrated botulinus toxin in liver extracts. They say that this has never been adequately tested as a means of postmortem diagnosis in man but should be tried whenever possible.

From the laboratories of the Los Angeles County Hospital and the departments of pathology and bacteriology of the University of Southern California School of Medicine.

REPORT OF CASES

Three fatal cases are here presented in which the botulinus toxin was demonstrated in tissue extracts in all three and in the antemortem blood of one:

CASE 1.—B. A., a Mexican laborer aged 39, entered the Los Angeles County Hospital May 2, 1938, with the history of refusal to talk. Because of a long past history of epilepsy with psychosis the first impression was that of hysteria, but the possibility of a foreign body in the throat was to be ruled out.

Physical examination, including laryngoscopy, was apparently negative. Within the next few hours the patient became stuporous and was found dead seventeen hours after entry and forty-seven hours after onset of symptoms.

The gross and microscopic postmortem examination gave essentially negative results except for marked hyperemia of the kidneys and partial pulmonary atelectasis.

Dr. Cyril B. Courville made the neuropathologic examination and reported the finding of multiple hemorrhages, cortical and in the perivascular gray matter, with congestion of the small vessels, with diffuse acute changes of the small pyramidal cells of the cortex.

No etiologic diagnosis was apparent eighteen hours after autopsy but information was available that the father of the deceased was showing similar symptoms. This aroused the suspicion of botulism poisoning as a probable diagnosis for both patients and investigation was immediately started in an effort to (1) disclose any possible source of contamination of food and (2) to demonstrate, if possible, the toxin in the deceased and in the living patient.

Although a thorough investigation was made by the public health authorities, the source of the toxin could not be determined. In investigating the possibility of active toxin in the organs of the deceased twenty hours after necropsy and twenty-six hours after death 50 Gm. of liver was triturated and extracted with 50 cc. of physiologic solution of sodium chloride; 1 cc. of this extract was injected intraperitoneally into each of two guinea pigs, one protected with 0.5 cc. of mixed antitoxin (A and B). After thirty-six hours the unprotected guinea pig developed experimental botulism and died forty-two hours after injection. The protected guinea pig appeared normal at this time but suddenly died a few hours later without the development of any signs of botulism. Graded doses of this extract, when injected into mice several days later, gave conflicting results, the evidence being suggestive but not conclusive.

CASE 2.—J. A., the 78 year old father of the first patient, became ill twenty-four hours after the onset of his son's symptoms. On admission his rectal temperature was 99 F., pulse rate 126 and respiratory rate 18 per minute. He was conscious and in no apparent pain but was having difficulty in breathing and swallowing and was able to answer questions only by nodding his head. The neck was not stiff and the pupils reacted to light, but paralysis of the internal rectus on the right was evident, as well as paralysis of the eleventh and twelfth cranial nerves and weakness of the intercostal muscles. The heart tones were normal. The blood pressure was recorded as 190 systolic, 120 diastolic. The blood Wassermann and Kahn reactions were negative. Although apparently in a terminal condition the patient was given 10,000 units of mixed botulism antitoxin (A and B) intravenously. Respirations ceased five hours after admission, the patient remaining alive in a Drinker respirator for another hour and dying six hours after entry and sixty hours after the onset of symptoms.

Blood collected at the time of admission to the hospital prior to antitoxin administration was tested for the presence of botulinus toxin in the following manner: Ten mice, five of which had been previously injected (fifteen minutes) with botulinus antitoxin (A and B) were injected intraperitoneally with 0.5 cc. of the citrated blood. At the end of thirty-six hours one unprotected mouse died and the remaining four showed symptoms of experimental botulism, viz. shallow breathing, muscular spasms, especially of the abdominal muscles, and later paralysis of the hind limbs and prostration. Three mice died in forty-eight hours and one sixty hours after injection. All of the protected mice survived without symptoms.

Necropsy in the second case was performed nineteen hours after death. Apart from arteriosclerotic changes consistent with the patient's age, the gross appearance of the viscera and tissues was similar to that of the first patient, with moderate hyperemia throughout, particularly in the meninges and kidneys.

Dr. Courville reported that the brain showed acute congestion with possible meningovascular syphilis.

Postmortem laboratory study in this case was more definite and enlightening. *Clostridium botulinum* was obtained post mortem on culture of stool and tracheobronchial secretions. Triturated liver extracted with saline solution yielded botulinus toxin, type A, as proved by mouse injections.

CASE 3.—R. C., a man aged 32, a Mexican, entered the hospital Feb. 6, 1939, with a three day history of dizzy spells, generalized weakness, sore swollen tongue and inability to talk. The patient was mentally alert. The rectal temperature was 99.2 F., the pulse rate 110 and the respiratory rate 24. No ocular disturbance was noted. The only positive manifestation was a reddened pharynx.

Twelve hours after entry the patient showed symptoms of respiratory failure and died within forty-five minutes.

Twelve hours after death an autopsy was performed by Dr. George Fein. The pathologic changes were confined to pulmonary atelectasis and moderate meningeal and visceral congestion. Cultures of the gastrointestinal tract and various organs were negative for *Clostridium botulinum*. Blood serum and spinal fluid in doses up to 1 cc. were injected into mice with negative results. However, a saline extract of triturated liver when injected into mice in doses of from 0.5 to 1 cc. produced experimental botulism with death in thirty hours with the larger dose and more than thirty hours with the smaller. Protected mice showed no symptoms.

Additional history was later available, indicating that on February 2 the patient had eaten one fig, which was home canned, and remarked that it was sour. The remaining figs had been discarded and therefore were not available for study.

In three recent nonfatal clinical cases seen in this hospital, circulating toxin could not be demonstrated. The attempts were made on the day of diagnosis, these being the third, fifth and eleventh day of illness respectively. The source of poisoning was traced to home canned string beans in two separate cases. Material was not saved for study but chickens partaking of the discarded food in both instances developed fatal limberneck and were in turn destroyed. No source could be determined in the remaining case.

COMMENT

The demonstration of toxin in the blood of one and in the tissues in all three of our fatal cases was of particular value, since efforts to find the source of poisoning were unsuccessful. Toxin was extracted from the liver and proved by animal inoculation in each of the fatal cases twenty-six, nineteen and thirty-seven hours respectively after death. Knowledge of the relative affinity of the toxin for the various organs would have been desirable. In case 3 attempts to determine this were unsuccessful because of changes in the material due to delay (eighty-five hours).

Of our three fatal cases a clinical diagnosis of botulism was made in only one instance (case 2) and circulating toxin successfully demonstrated. In three nonfatal clinical cases circulating toxin could not be demonstrated.

The work of Bergman and his associates² appears to have proved that botulinus antitoxin neutralizes the circulating toxin in man, but no information is available as to its effect on tissue fixed toxin. In case 2 toxin was demonstrated in the liver even though 10,000 units of antitoxin (A and B) had been administered five hours before death. Unfortunately we neglected to determine the presence of toxin in the blood at necropsy.

The value of the serologic and tissue extract procedures should be recognized by the clinician and pathologist who have had difficulty in making an exact diagnosis in cases of botulism.

It is hoped that this report may stimulate an interest in the practical value of these procedures and that further observations may elucidate the various questions here raised.

SUMMARY AND CONCLUSIONS

1. Five outbreaks of botulism with three fatal and three nonfatal cases occurred within a period of ten months in Los Angeles County.

2. Circulating toxin was demonstrated in the blood of one patient by animal injection and its specificity (type A) determined by toxin-antitoxin experiments. Circulating toxin could not be demonstrated in three nonfatal cases.

3. Toxin was demonstrated in saline liver extracts in all the fatal cases.

4. The demonstration of circulating or tissue toxin as herein described should aid in the diagnosis of botulism and we believe that such attempts are indicated in all suspected cases of botulism.

TWO RELATED OUTBREAKS OF FOOD POISONING ATTRIBUTED TO A *SALMONELLA* ORGANISM

DAVID H. ANDREW, M.D., C.P.H.

FERDINAND A. KORFF, B.S.

AND

C. LEROY EWING

Directors of the Bureaus of Communicable Diseases, Food Control and Laboratories, Respectively

BALTIMORE

On June 14, 1938, several cases of acute food poisoning were reported to the city health department as probably having been caused by food or foods eaten at a wedding banquet on the evening of June 12. On interviewing the persons reported to be ill, we learned that others who had attended the banquet were similarly affected with acute gastro-enteritis. All told, 105 persons were said to have partaken of food at the banquet held following a wedding ceremony at a public hall in the city. By interviewing sixty-eight of the victims and through a questionnaire sent to sixteen persons residing out of the city, it was learned that seventy-nine persons were made ill. Two of the foods served at the banquet were eaten by all of the persons who became ill—cantaloup with blackberries and stuffed tomatoes with a liver paste. Simultaneously with this outbreak there were also reported several cases of illness with similar symptoms following a confirmation party held on the same day, June 12. At this party twenty-one children, ranging in age from 12 to 18 years, and two adults ate a meal that included celery with a filling of liver paste. Every one of these became ill. In neither outbreak were there any fatalities.

REPORT OF THREE TYPICAL CASES

The clinical course of several typical cases was supplied by the medical resident of one of the local hospitals:

CASE 1.—A housewife aged 38, admitted to the hospital June 15, complained of abdominal pain, vomiting and diarrhea. On Sunday June 12 she had attended a large dinner reception.

From the Baltimore City Health Department.

June 13 she had ten loose, watery stools without mucus or blood. Associated with diarrhea she also had abdominal cramps and vomited several times. The next day she felt feverish and the diarrhea continued. On admission the temperature was 102.4 F., the pulse 100, the respiratory rate 24 and the blood pressure 100 systolic, 80 diastolic. Physical examination was negative except for slight diffuse abdominal tenderness without muscle spasm or rigidity. The red blood cells numbered 4,400,000, the hemoglobin content was 92 per cent and the white blood cell count was 9,500. The urine was normal except for the presence of 2 plus acetone. In the hospital the patient was given 500 cc. of 10 per cent dextrose intravenously. The diarrhea yielded to camphorated tincture of opium and bismuth subnitrate. June 17 the temperature was normal and remained so until discharge. Examination of the stool showed no mucus, pus or blood. The patient was discharged June 20.

CASE 2.—A school boy aged 13, admitted to the hospital June 15, 1938, complained of abdominal pain and diarrhea. June 12 he had attended a reception. June 13 he began to have diarrhea and severe abdominal pains and he vomited twice. The day before admission his temperature reached 102 F.; on admission it was 100.4 F., the respiratory rate 24 and the blood pressure 108 systolic, 70 diastolic. Physical examination was negative except for slight diffuse abdominal tenderness. The red blood cells numbered 5,010,000, the hemoglobin content was 98 per cent and the white blood cell count was 6,450. Examination of the urine was negative. The stool contained no blood, mucus or pus. There was an elevation of temperature until June 16. During this time diarrhea continued, with six stools a day. June 18 the temperature was normal and the diarrhea yielded to camphorated tincture of opium and bismuth subnitrate. The patient was discharged June 20.

CASE 3.—A schoolboy aged 8 years, admitted to the hospital June 15, 1938, complained of abdominal pains and diarrhea. He had attended a large dinner reception June 12. The next day, June 13, he had severe abdominal cramps and from ten to fifteen watery stools. The next day he vomited a number of times and felt feverish. On admission his temperature was 100.4 F., the pulse 104 and the respiratory rate 24. Examination was negative except for slight tenderness in the epigastrium. The liver was felt one fingerbreadth below the right costal margin. The red blood cells numbered 5,300,000, the hemoglobin content was 115 per cent and the white blood cell count was 10,350. Examination of the urine was negative. On the day after admission the temperature was normal, diarrhea

Vegetable salad (slaw).....	66	62	4
Potatoes, peas and carrots.....	74	70	4

and vomiting ceased and the patient complained only of occasional abdominal pains. He was asymptomatic June 17 and was discharged June 18. Examination of the stool showed no mucus, pus or blood.

The majority of the other cases were strikingly similar in their clinical course and all the patients recovered completely after about six days. The death of one of the persons ill was reported about two weeks later, but it was found that this patient, aged 55, had completely recovered from the food poisoning more than a week before and died of a chronic cardiac condition.

There was no evidence or history of blood in the feces of any of the patients.

The average incubation period was about nineteen hours. Most of the persons became ill the day after the meal at about 6 p. m. The shortest incubation period was four hours (reported in one case) and the longest incubation period was sixty-seven hours after the food had been eaten.

EPIDEMIOLOGY

The food for both the banquet and the confirmation party had been prepared on the same day by the same private caterer, a person previously unknown to the health department, who operated from a private home.

TABLE 2.—*Confirmation Party*

	Total	Ill	Not Ill
Total attending party interviewed.....	23	23	0
Celery stuffed with chopped liver.....	23	23	0

Orange ice.....	20	20	0

The food for the banquet consisted of cantaloup with blackberries, celery, olives, soup, baked chicken with stuffing, potatoes, peas and carrots, vegetable salad and tomatoes stuffed with liver paste. The only food served at the confirmation party that was served at the banquet was the chopped liver paste, with tomatoes in the first instance and with celery in the second instance.

In preparing the food the chickens were drawn and the livers of the fifty-five chickens were parboiled, chopped in a meat grinder and mixed with hard boiled eggs, chicken fat and soaked bread. This filling was prepared, according to the caterer, at about 8 or 9 o'clock on the morning of June 12. It was then mixed by hand by three food handlers. The rooms in which the food was prepared were in the basement of a private dwelling, and these rooms were lacking in sanitary conveniences and adequate refrigeration. The outdoor temperature on June 12 reached a height of 94 F. The liver filling, in fact, was not refrigerated at all from the time it was mixed in the morning until it was served at about 7 p. m. The quartered tomatoes were filled with the liver mixture after being transported to the banquet hall. They were served as a course with other food.

The results of the interview with eighty-four of the persons who attended the wedding banquet with regard to the food eaten and whether or not they were ill are shown in table 1.

It will be noted from table 1 that every one who ate the chopped liver became ill. As further evidence that the chopped liver was the cause of the outbreak, the five persons who attended the wedding dinner and did not eat of the tomatoes with liver filling in each instance gave a report of not having become ill.

The results of the epidemiologic investigation of the twenty-three persons who attended the confirmation ceremony are shown in table 2.

It is interesting to note that twenty-three persons attended this confirmation party, of whom only two were adults. As stated, every one present became ill and every one present ate celery stuffed with liver paste. This was the only item of the menu eaten by all who attended the party. One adult at this party ate only a

single portion of the meal, namely the celery stuffed with liver paste. This person became ill. Several persons present failed to eat at least one of the other foods served. This is in contrast to the wedding banquet, where a few failed to eat the liver filling and did not become ill. One adult who attended the wedding banquet was on a diet and therefore did not eat the infected food; several were late for the meal and the liver product had all been eaten, and these were spared the illness.

Investigation failed to reveal anything of significance at either party with regard to the age or sex distribution of the cases. The wedding banquet was attended primarily by young white adults of both sexes with a few of the older members of the families present. The confirmation party was attended by twenty-one children and two adults. Again, all who ate the liver paste filling became ill.

The food handlers who prepared the food—two Negro and one white all female—stated that they ate portions of all the food during the preparation on the morning of June 12 between 8 and 9 o'clock and did not become ill. This perhaps indicated that either the chopped liver became infected after preparation and during the storage period or the infection occurred during the preparation and increased during the storage time, probably as a result of the very warm weather.

LABORATORY OBSERVATIONS

Owing to the delay in receiving reports of the outbreaks, no food with the exception of some olives was available for laboratory examination. The olives were found to be practically sterile. Fecal specimens from the three food handlers, from four other members of the caterer's household and from twenty of the persons who were made ill were obtained and submitted for bacteriologic examination. The fecal specimens from the three food handlers, from one of the members of the caterer's household and from fourteen of the patients all contained organisms which were identical and which were found to belong to the *Salmonella enteritidis* but were not agglutinated by three different *Salmonella enteritidis* antisera. They were agglutinated, however, to a fairly high titer by an antiserum of *Salmonella newport*. Transfers of some of the cultures were sent to the Standards Laboratory of the Medical Research Council at Oxford, England. This laboratory reported that the cultures were identical with one another and with the *Newport* type.

COMMENT

The method by which the food became infected in these outbreaks cannot be definitely determined. Several theories may be advanced as to what actually occurred. Many investigators do not believe that carriers or subclinical cases of *Salmonella* infections are usually the means of spread of this disease. It is known that fowls and other animals are infected with one or more of the many organisms making up the *Salmonella* group. Therefore, several possibilities present themselves. First, that the chickens were infected at the time of purchase with a member of the *Salmonella* group of organisms and through careless and multiple handling the cooked chicken, especially the livers, became infected, the infection being transmitted to the food either by human hands or by improperly washed utensils. The warm weather, the type of food and the lack

of refrigeration, of course, made ideal conditions for the growth of the organisms. Second, rats were suggested as the mode of spread of this infection. Rat traps and evidences of rat infestation were noted in the cellar of the caterer. It was thought, therefore, that possibly the rats, acting as carriers, contaminated the food and were the basic cause of the infection.

This is all pure conjecture and, while proper refrigeration of perishable foods and cleanliness are both important and absolutely necessary, as shown in this case, another source of possible contamination of food may be present; that is, the contamination of well cooked food by poorly washed utensils or dirty hands directly from freshly killed fowl which had been previously infected by one of the organisms of the *Salmonella* group. Edwards¹ stated that *Salmonella newport* had never been reported in the United States prior to 1938. He has since, however, isolated this organism from the intestinal tract of a hen and also from a pullet, both of which were in flocks in which there was a high mortality.

SUMMARY

1. June 13, 1938, two large groups of persons became ill with gastro-enteritis, one group after a wedding banquet and one after a confirmation party.

2. The clinical course of all the cases investigated was strikingly similar, and recovery was complete after about six days.

3. The meals in both instances were prepared by a caterer previously unknown to the city health department. Sanitary conditions at the place of preparation were poor, the refrigeration was completely inadequate and the outside temperature reached 94 F. on the day the food was prepared.

4. Epidemiologic investigation definitely revealed that the liver filling was the cause of the illnesses at both affairs. For various reasons several persons who attended the wedding banquet did not partake of the liver and did not become ill. All who attended the confirmation ceremony ate the liver and all became ill.

5. None of the foods served, except the olives, were available for laboratory examination. Fecal specimens were obtained from twenty-seven persons. From stools of fourteen patients and of four other persons associated with the preparation of the food a *Salmonella* organism was isolated which was identified as *Salmonella newport*.

6. The methods of preparation and storage of the food and the warm weather were in themselves enough to cause the growth of bacteria and the production of toxins. Another source of infection has been suggested. Possibly some of the chickens were infected with a member of the *Salmonella* group at the time of purchase. The uninfected poultry may have been well cooked and properly prepared by the caterer. Unwashed utensils or human hands which had not been properly cleaned may have been the mode of transmission of the organism. The evidence of rat infestation at the place of preparation of the food gave rise to the thought that possibly these rodents had been the source of contamination of the food.

7. The outbreak again emphasizes the need for cleanliness, carefulness, refrigeration and experience on the part of persons engaged in the preparation of food for any large number of persons.

EXCISION OF THE PATELLA IN
ARTHRITIS OF THE
KNEE JOINT

E. J. BERKHEISER, M.D.

CHICAGO

For many years the apparent futility of all forms of conservative management of relatively severe arthritis of the knee joints has stimulated the search for a possible surgical procedure which is less radical than fusion or synovectomy of the involved joint. Every orthopedic surgeon can immediately recall the vast number of patients he has treated for arthritis of the knees who after traction, immobilization by casts in the position of function, physical therapy, vaccines and eradication of foci of infection would return at variable intervals complaining of pain on motion, stiffness and recurring deformity. Careful elicitation of the patient's complaints almost invariably results in the information that the greatest pain is localized in the anterior part of the knee and is aggravated by active attempts at extension. This motion when possible is almost invariably associated with subpatellar crepitation and not infrequently is associated with gross, irregular, cog-wheel-like movements of the patella.

The increasing frequency of case reports concerning the excision of the patella for fracture and the clinical and experimental observations of Brooke in regard to the physiology and function of the knee joint following the excision of the patella for fracture led me to believe on a priori evidence that the same procedure would be applicable in carefully selected cases of arthritis of the knee joint. Before the publication of Brooke's report a personal communication from Mr. Constantine Lambrinudi informed me that he had used this procedure in five cases of arthritis of the knee joint, three of which were hypertrophic and two of the chronic rheumatoid type. He stated that he was highly satisfied with the resulting relief of pain and improvement of function.

Operative removal of the patella, either total or partial, has been done by many surgeons in the treatment of fractures of this bone.

Thomson¹ advocated the removal of the small fragments in comminuted fractures of the patella in a paper before the Section on Orthopedic Surgery in 1934.

Blodgett and Fairchild² reported a series of cases of fracture of the patella in which either the patella or some of the fragments were removed at operation. This procedure gave uniformly good results.

Several British surgeons employ it as a routine measure in treating fractures of the patella.

Brooke,³ of the Royal West Sussex Hospital, Chichester, England, has been employing this measure for a number of years and has reported thirty cases in which he has removed the patella for simple fracture, twenty-two patients being men and eight being women.

Hey Groves⁴ stated that "Brooke's assertions seemed absolutely incredible. However, examination of the operative results showed that they were correct. He undertook some anatomic investigations and found that

the quadriceps tendon passed well in front of the patella to join the patellar tendon. Hence the method suggested is perfectly justified."

Tippett⁵ stated that he agrees with the conclusions which Brooke has arrived at after using the procedure in three cases.

Others who have reported on the operative removal of the patellar fragments are Bissell⁶ and Whitelocke.⁷

In a personal communication of Dec. 31, 1938, Mr. Herbert Britain informed me that he has used this procedure fifteen times for fracture of the patella, ten times for osteo-arthritis, once for recurrent dislocation and once for osteomalacia. He feels it wise to confine the operation to patellar-femoral arthritis.

Excision of the patella for fractures associated with gunshot wounds of the patella was performed during the great war. The patella has also been removed for such conditions as primary osteomyelitis, tuberculosis, tumors and congenital dislocations.

Burrows⁸ has seen two cases in which different surgeons had removed the patella for recurrent dislocation. In each case the symptoms of recurrent dislocation of the extensor apparatus continued after the operation.

Tippett is surprised that more correspondents have not commented on what he considers the most important application of excision of the patella, namely, to relieve pain in early osteo-arthritis in the knee joint.

This is the particular phase to be considered in this paper. Although I have not had occasion to advise this procedure in cases of early osteo-arthritis, I feel that the procedure has a definite place in the therapeutic armamentarium of the surgeon in the treatment of certain cases of arthritis of the knee. The rationale depends on a thorough understanding of the anatomy, physiology and mechanics of the knee joint.

MORPHOLOGY OF THE PATELLA

Brooke has concluded that the patella is a sesamoid bone but there is no evidence that its development is a response to a functional need or that the bone serves any useful function when formed. He thinks it is an integral part of the skeleton phylogenically inherited.

Bernays and Kazzender have shown that the patella is neither developed nor situated in the quadriceps tendon but that its development is independent of and occurs behind this tendon.

This can readily be seen in a study of the knee joint of a 50 mm. embryo. Later in the development of the embryo the patella obtains attachment to the tendon.

COMPARATIVE ANATOMY OF THE PATELLA

Studies in comparative anatomy indicate that in animals function does not influence the development and growth of the patella. The functional activity of the quadriceps tendon in man increases from birth till adult life, and the relative size of the patella if governed by function should be proportionately larger in the adult. Actually it is relatively smaller. In the sloth, the mole and the echidna, all slowly moving animals, the bone is well developed, while in the fox, the deer and the leopard, all rapidly moving animals, it is proportionately small. In the kangaroo, in which there is enormous development of the quadriceps in conformation to the animal's mode of progression, the bone is completely absent.

8. Burrows, H. Jackson: *Brit. M. J.* 1: 418 (Feb. 19) 1938.

De Vries has deduced from her studies that the bone is in the process of reduction in much the same way that the fibula is and considers this a strong point in favor of phylogeny as the determining factor for its presence.

In contrast to the concepts just cited must be considered the well known fact that in the human being born with genu recurvatum the patella fails to develop normally until the deformity is corrected and natural functional stresses are allowed to occur. This indicates that the size of the patella is governed in man by function. Hence it seems that for the present phylogeny may be considered as the determining factor for the presence of the patella and function the determining factor for its size in man.

Fig. 1 (case 2).—Appearance of soft tissue shadow of patellar and quadriceps tendons.

ROLE OF THE PATELLA IN THE MECHANISM OF THE KNEE JOINT

Lickey has pointed out that the patella apparently fulfils two functions in the knee joint. He suggests that the patella forms a much more suitable pulley for motion around the condyles of the femur than the tendon itself, because the upper end of the patella is kept in a plane well in front of the axis of flexion and extension. He considers the second function of the patella that of a lever of the first order acted on by a force at each end with a fulcrum at a varying distance between the two. His explanation of the mechanics of the knee joint is probably correct, and the pulley and leverage action with its alteration of the fulcrum in the knee joint is probably advantageous.

Theoretically and actually the presence of the patella enhances the power of the quadriceps and therefore serves a useful purpose. It must follow logically that

interference with its leverage action and alteration of the fulcrum would theoretically detract from the mechanical advantage in assisting movements at the knee joint. The problem is one of relativity because the patella is not essential for good knee function. This is shown by instances in which the patella is congenitally absent and will be shown by references to surgical literature concerning cases in which the patella has been operatively removed.

I have noted marked hyperplasia of the patellar and quadriceps tendon which began with the institution of active functional use of the extremity subjected to operation and continued for a variable period in each case. This was so marked in some cases that it could easily be seen on inspection. The change in the patellar tendon was demonstrated by a comparison of preoperative and postoperative roentgenograms, shown in figures 1 and 2.

EXPERIMENTAL INVESTIGATION OF THE IMPORTANCE OF THE PATELLA IN MOVEMENTS AT THE KNEE JOINT

Brooke investigated the importance of the patella in movements at the knee joint relative to the effects of its removal for fracture. From the postmortem room he obtained a number of knee joints in the fresh state. These were freed from all muscular attachments, with the exception of a short length of quadriceps tendon which was left attached to the patella. The specimens were then mounted on a stand in such a manner that the quadriceps tendon was connected by a cord passing over a pulley to a weight. A second weighted cord was attached to the anterior surface of the tibia and in turn passed over a reducing pulley and attached to a lever which recorded on a revolving drum. By means of this experimental setup Brooke determined that the absence of the patella enhanced the speed of motion at the knee joint, so that the time taken for movement of the leg from the horizontal to the vertical plane was about half the time required with the patella in situ. He also noted that when the leg was put through a complete range of motion, from active flexion to full extension, the time taken was less when the patella was excised than when it was in place.

EXCISION OF THE PATELLA IN CASES OF ARTHRITIS AND ITS EFFECT ON THE FUNCTION OF THE KNEE JOINT

It has been noted that moderate to marked improvement in function has resulted in each knee joint from which the patella has been excised for arthritis of the knee. The increase in range of motion and strength of the quadriceps group of muscles has been sufficient to be demonstrated by simple mechanical appliances. One appliance consists of a 5 pound weight so attached to the ankle by rope and pulleys that extension of the leg on the thigh lifts the weight a measured distance. It is then an easy matter to measure the relative strength of the extensors of the leg subjected to operation as compared with the strength of the extensors of the intact extremity, which is used as a control. In each case the power of extension of the surgically treated extremity was greater than in the extremity not so treated. This test was used only in cases of bilateral involvement in which operation was performed on the more severely involved extremity.

Another simple mechanical device was utilized to corroborate these observations. This was a lever

attached to a baseboard by a hinge. A spring balance scale was interposed between the ankle and the lever and was connected with each by a cord. The extremity to be tested was allowed to assume 90 degrees of flexion and in that position the toes of the foot were allowed to touch a wall lightly. The patient was instructed to hold the toes against the wall while force was exerted

against the free arm of the lever. The force necessary to pull the toes from the wall was then measured on the scale.

The same procedure was carried out on the intact extremity in cases of bilateral involvement. In each case it was found that the extremity could withstand greater pull than the extremity on which operation had not been performed.

My report concerns eleven cases of excision of the patella for arthritis of the knee. I feel that this procedure is not specific treatment of arthritis as such but rather a means of eradicating a definite mechanical impediment to function which results from the changes secondary to chronic arthritis.

The aim of the procedure, therefore, is not to obtain a

perfectly normal knee joint but rather to relieve the patient from having pain on making attempts at extension and to increase the range of motion. Thus the indications are rather clearly defined and must be closely followed if the procedure is not to fall into ill repute. For the purpose of this study I used only cases which satisfied the following criteria:

1. The duration of the disease was several years.
2. Repeated periods of conservative management resulted in improvement, and there were recurrences.
3. When bilateral lesions were present the more severely involved joint was chosen while the other was observed as a control.
4. The disease was quiescent at time of operation.
5. There was definite x-ray evidence of arthritis (hypertrophic or rheumatoid) such as diminution of the width of joint spaces and presence of marginal exostoses (fig. 3).
6. It was evident that extension of the leg on the thigh to 160 degrees would be obtained postoperatively.
7. The mental and physical state of the patient was good enough so that he would be able to stand and walk postoperatively.

ETIOLOGIC FACTORS

I decided early in the study to select all cases suitable for operation regardless of the primary etiologic factor involved. This was decided on because, as previously stated, the procedure was designed to eliminate mechan-

ical impediment to the function of the knee joint and was not aimed primarily against any specific disease state. Hence I included in this study four cases of atrophic arthritis, three cases of hypertrophic arthritis or combined arthritis, two cases of gonorrheal arthritis and two cases of traumatic arthritis.

There were four men and seven women. The youngest patient was 35 years old and the oldest 64 years. The average age was 49 years. The duration of the disease was from eighteen months to twenty-three years.

PATHOLOGY

At the time of operation the gross pathologic changes presented by arthrotomy were sufficient to explain the impairment of the function. These changes were present in the synovia, the articular cartilage of the patella and the femoral condyles as well as in the tibio-femoral joint.

In five cases hypertrophic synovitis was marked; in three cases the suprapatellar pouch was obliterated by a fibrotic fusion of its synovial walls. This apparently intimately connected the quadriceps tendon with the anterior aspect of the femur, which with the osseous changes present resulted in a loss of free motion of the quadriceps tendon and patella.

In eight cases osteophytes on the articular aspect of the patella impinged on corresponding osteophytes and marginal exostoses of the underlying femoral condyles.

Fig. 2 (case 2).—Appearance of patellar and quadriceps tendons after excision of the patella.

Fig. 3.—Typical appearance before operation.

In the articular cartilage of the femoral condyles there was frequently definite evidence of osteochondritis, with degeneration and loosening of circumscribed areas of cartilage from the underlying bone. In other cases the articular cartilage of the femoral condyles was definitely involved by panus formation, with subsequent thinning and in places loss of the articular cartilage. In these

areas the subchondral bone had definitely undergone hyperplasia resulting in elevated areas, so that an apparent plateau was formed which acted as an osseous block to the normal excursion of the patella.

SYMPTOMS

In general the symptoms were pain in the knees on attempts at active motion and loss of function, which the patients usually attributed to pain but was often found to be a manifestation of deformity as well as pain. No effort was made to itemize the individual symptoms. Flexion deformity was present in ten of the eleven cases and restriction of motion was present in all the cases.

PREOPERATIVE TREATMENT

It was considered essential that some mobility of the joint be proved possible before operative intervention was attempted. In cases in which a relatively fixed flexion deformity of less than 160 degrees was present it was considered advisable to obtain at least 160 of extension by traction, by wedge casts, by turnbuckle casts employing Turner irons or by Mommmsen's quengel method. It was deemed advisable to eradicate any foci of infection which might be present and might have an etiologic relationship to the arthritis.

OPERATIVE TECHNIC

The usual forty-eight hour preoperative preparation is employed. The operation is performed under a tourniquet. A vertical incision about 6 inches in length is centered over the patella. The skin margins are protected by towels. The incision is then carried down to the patella, which is enucleated by sharp longitudinal dissection of the tendinous fibers of the overlying quadriceps tendon.

On freeing the anterior surface of the patella the capsular attachment and synovia at the margins of the bone are easily severed. The longitudinal incision in the quadriceps tendon is then closed with a continuous chromic catgut suture. The superficial tissues are closed in layers without drainage.

On closure of the operative wound the limb is passively extended within the limits of safety. It is noted that the range of flexion is immediately definitely increased.

Postoperative immobilization either in a cast or by traction in a Thomas splint is used for a period of one week to ten days for the patient's comfort. Immobilization by massive cotton dressing might be as efficient.

POSTOPERATIVE TREATMENT

At the end of ten days the patient is encouraged to stand and bear weight and begin walking increasing distances daily.

In this series of cases there was no physical therapy other than active functional use of the extremity because of the inability of these patients to travel the long distances daily to the hospital. However, the results probably would have been attained at an earlier date if proper physical therapy could have been utilized.

In most of the cases in which the disability has been present over an interval of years, it has been deemed advisable to initiate weight bearing with the use of a posterior molded splint extending from the gluteofemoral crease to the ankle. This has been employed because of the marked atrophy of the thigh group of muscles.

Also these older patients are timid and require a little support in standing and walking to reestablish their confidence. This splint is dispensed with while the patient is abed and as soon as the postoperative reaction has completely subsided. It has not been necessary to use the splint longer than a few weeks.

COURSE AND PROGNOSIS

In general, all these patients have shown progressive improvement in ability to walk from early postoperative observation to the present time, which I attribute to diminution of pain, greater ability to maintain extension and greater range of motion. This observation is of interest as the improvement in ability to walk has occurred even though the condition was bilateral and only one of the extremities has been operated on. In support of this assertion is the fact that all the patients with both knees involved have repeatedly returned and requested a similar operation for the disability of the other knee.

In general the prognosis following excision of the patella for arthritis of the knee is good in regard to the relief of pain and increased function. It has been noted that in chronic multiple arthritis the general state of health is improved and also the joint manifestations of the disease are often ameliorated by changing the status from that of a helpless bedfast or wheel chair patient to that of an ambulatory person. This improvement was noted in each of my patients.

REPORT OF CASES

CASE 1.—P. P., a man aged 35, entered Cook County Hospital Oct. 25, 1937, because of inability to walk resulting from painful swollen knee joints. This patient had been employed as an orderly at the hospital during the previous six years. Four years before admission he had his first attack of arthritis, during which all his joints were involved. After his first attack he was repeatedly readmitted to the hospital because of recurrence of arthritis. On previous admissions flexion deformities of the knees were treated by traction and casts. During the last six months he had no recurrence of acute symptoms, and he returned at this time particularly for treatment of the knees since he could not walk because of pain and deformity.

The essential abnormalities were swelling of the knees and periarticular thickening of the soft parts, which were most marked on the right side. The left knee was held in 20 degrees and the right in 30 degrees. There was palpable crepitation of the joints on active motion. Flexion was possible to 90 degrees but was associated with pain.

X-ray study of the right knee revealed a narrowing of the patellar-femoral and the tibiofemoral joint spaces. A small osteo-arthritis spur was present at the distal margin of the articulating surface of the patella and at the anterior-superior margin of the femoral condyles. An osseous mass was present at the medial margin of the medial condyle (Pellegrini-Stieda disease).

On October 28 the right patella was excised and the following gross pathologic appearance of the knee joint was observed:

The synovia of the suprapatellar pouch was markedly hypertrophic and bright reddish brown. The articular surface of the patella was rough and revealed many areas, up to 8 mm. in diameter, devoid of cartilage. There was an exostosis at the inferior margin of the patella. The cartilage of the femoral condyles revealed osteochondritic areas, measuring up to 1 cm. in diameter, in which the cartilage was yellowish white and could be easily depressed by an instrument.

Microscopic examination of the synovia revealed round cell infiltration and focal hemorrhagic areas. Synovial cells were moderately hyperplastic.

The postoperative course was uneventful. The patient was discharged November 16. He was last seen April 3, 1939;

at that time the surgically treated right knee was relatively painless and could be actively extended to 170 degrees and flexed beyond a right angle. He has been able to walk since leaving the hospital, placing most of his weight on the right leg.

He desires a similar operation on the other knee, as he is of the opinion that he could resume his occupation thereafter.

CASE 2.—L. S., a man aged 48, entered the hospital March 29, 1938, because of inability to walk and pain in the knees, elbows and hands. He had his first attack of arthritis six years previously and had been a patient in the hospital on three previous occasions for the same trouble. On his first admission in 1932 he had had many teeth extracted and had received a series of typhoid vaccine injections intravenously as treatment for his arthritis. In 1934 and in 1936 he was again treated in the hospital for flexion contractures of the knees. This treatment consisted of traction, which was followed by the application of casts until the contracture was corrected.

He returned at this time because of recurrence of the flexion deformity, which was associated with such marked pain that he could not walk. The essential abnormalities were diffuse swelling and periarticular thickening of both knees, which were most marked on the right side. There were a 35 degree flexion deformity of the right knee and a 20 degree flexion deformity of the left knee. There was free flexion to 50 degrees bilaterally. Active extension was associated with marked pain, and palpable crepitation was present over each patella.

X-ray study revealed narrowing of the patellar-femoral and the tibiofemoral joint spaces. The articular surface of the lateral condyle of the right femur was flattened and showed circumscribed areas of decreased density with some marginal areas of sclerosis and irregularity.

On March 31 the right patella was excised. During anesthesia the left leg was manipulated into complete extension and immobilized in extension by a circular plaster cast.

The gross pathologic change noted at the time of arthrotomy was loss of cartilage on the articular aspect of the patella, and the exposed bone was eburnated. The synovial lining of the suprapatellar pouch was pale pink and moderately thickened.

The articular cartilage at the margins of the femoral condyles was eroded in places, exposing the underlying subchondral bone. Microscopic sections of the synovia revealed round cell infiltration.

This patient was last seen April 19, 1939. He has been walking since leaving the hospital April 13, 1938. He has active extension of the right leg to 170 degrees and free flexion to 100 degrees. Motions are almost painless and he has repeatedly requested a similar operation on the left knee.

SUMMARY

1. Excision of the patella was utilized in the treatment of eleven cases of chronic arthritis of the knee joint.
2. The results of this operation have been satisfactory in eight cases and only fair in three, which were not well selected. One patient was an old Negro woman with peculiar psychic traits who was operated on twenty months before this report. Another had a latent gonorrheal pelvic infection, and the third was operated on too recently (two months ago) for one to be certain of the result.
3. In this series of cases there has been no death, complication or aggravation of the original condition.

CONCLUSIONS

Chronic arthritis of the knee joints with disability which has not adequately responded to repeated applications of conservative therapeutic measures is a prevalent condition.

For this deplorable state I offer a possible operative procedure, i. e., excision of the patella, which others

have used and which at this time seems to be of definite value.

As far as can be determined to date, with proper regard to the definite indications for the operation there is little danger either to the patient or to the extremity.
122 South Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. A. H. MEYER, Memphis, Tenn.: I have not had any experience with the removal of the patella. I am therefore placed in a peculiar position in opening this discussion. I have always been able to cope with comminuted fractures of the patella by removing a few small fragments and using a purse-string suture to hold the remaining ones. The results have been uniformly satisfactory. The procedure as suggested by Dr. Berkheiser appears to me to be a bit radical, but in view of his results one cannot with fairness say that he is on the wrong track. If one considers that the patella is a sesamoid bone, then nature has placed the patella here for a definite purpose from a functional and evolutionary standpoint. A patella also helps to form the capsule of the knee joint and is the only bone in the body which does this. In view of the fact that the patella is therefore a contributing part in the formation of the knee joint, it would appear that its removal would certainly upset the anatomic structure of this very important weight bearing joint. I have always felt that the patella gives greater leverage to the function of the quadriceps muscle and acts as a direct fulcrum. To remove this would appear to me on the surface not only to weaken the joint but to put the extensor power of the quadriceps at a distinct disadvantage. From the clinical angle, I can readily understand that with excessive bone growth both on the patella and on the articular edges of the femur the patella under these circumstances would mechanically block motion in the knee joint and also, with the incongruity of the articular surfaces, produce pain on movement; therefore, on these bases removal of the patella would obviate these factors. About eighteen months has elapsed since Dr. Berkheiser's first operation of this nature, and I feel that sufficient time has not yet passed to tell what the final result will be. I mean that functionally it is too early to come to a conclusion and evaluate properly this method. More time should be given and these cases followed to decide ultimately the true value of the operation. Far be it from me to disparage Dr. Berkheiser's idea and his procedure. I merely wish to say that excision of the patella appears to be a rather radical operation; nevertheless, may I say that Dr. Berkheiser's end results are most illuminating and in this country he may be the pioneer who has led us across the new frontier to the fertile plains of peace and comfort for these unfortunate suffering individuals.

DR. JACOB KULOWSKI, St. Joseph, Mo.: This procedure did seem a little radical at first, but the subject has been worked up so thoroughly that the procedure should be given very careful consideration. I was particularly impressed with the indications for operation. My experience has been with certain cases of so-called counter mollities of the patella, which I described about six years ago, and I mention this because in these cases—there were three or four at the time—the lesion was confined solely to the patella articular cartilage, and in those cases the entire articular cartilage and the contiguous bony surface were resected. At the time I thought that the procedure was a little radical. I think now that perhaps it was not radical enough.

DR. FRANK G. MURPHY, Chicago: With Dr. Berkheiser's permission, I will answer Dr. Meyer's question. Recently I examined a case of bilateral osteo-arthritis of the knees with Dr. Berkheiser. One side had been operated on. There was fairly free movement on this side but I did not think the strength in the knee was quite equal to that of the untreated side. However, the extent of motion was much increased and the motion through this range was freer than that on the other side. The patient expressed a desire to have the operation

performed on the other knee when he got around to it. A question I wish to ask Dr. Berkheiser is Do you perform any further operative procedure in these cases, such as synovectomy or trimming away of some of the osseles that seem to limit motion in these knees? Another matter that deserves special mention is that the scope of application of this procedure is not limited to arthritis or to fractures of the patella. I have excised the patella in doing an arthroplasty of the knee joint. I think it simplifies the operation and allows a number of short cuts by eliminating the necessity of trimming out and placing fascia between the patella and the underlying condyles.

DR. J. ALBERT KEY, St. Louis: It seems to me that Dr. Berkheiser did not mention the work of Dr. Blodgett of our own society, who is a pioneer in the removal of the patella and reported a series of cases before this group, all of which I believe were for fractures of the patella. Also Dr. Thompson has been progressively removing the patella for fracture for some years. Theoretically this operation is a poor operation but practically it works. That is the important thing. When I read Brook's paper I just did not believe it, but I got into a hole not long ago in lengthening a quadriceps tendon by Bennett's method and to my surprise found the patella ankylosed by bone to the femur, which I had not known until I was about half through operating. I took the patella out and the patient does not miss his patella at all; in fact, he is better than he would be had I left it in.

DR. JOHN P. STUMP, New York: The primary thing I want to know is what Dr. Berkheiser means by "conservative management preoperatively." As I saw his roentgenograms, he showed some knees with considerable destruction of the joints apparently due to atrophic arthritis, and one or two cases with osteoarthritic changes, and some with but little bone change. I have not removed patellas for any type of arthritis, so I have no experience in that regard; however, I have been interested in patients with painful knees who present symptoms of tenderness anteriorly and pain posteriorly, as the author described. I have relieved many of them by correcting the static strain. A pronated foot causes a tremendous strain on the internal lateral ligament and that strain in turn causes an irritation of the synovial membrane, causing a synovitis which gives symptoms such as Dr. Berkheiser described. I have given tremendous relief to the patients and in a number of cases if "cure" were not such a big word I would say "cured" them by merely correcting their weight bearing and removing the strain from the internal lateral ligaments. I should like to ask Dr. Berkheiser whether he has included this type of treatment in his preoperative management.

DR. GARRETT PIPKIN, Kansas City, Mo.: Lambernudi in London hunted up two cases for Jesse Nielsen and me a year or two ago in which operation had been done several years before. Both patients had good functional results, considering the amount of destruction the knee had suffered prior to operation.

DR. E. J. BERKHEISER, Chicago: It is true that this operation seems a little radical and unanatomic, but we are all familiar with the removal of the sesamoids around the great toe and other places without any particular harm being done. So far as the strength of the knee is concerned, these knees were no good to begin with. They had strength but they were painful. After their removal they had a sufficient amount of strength so that the patients could walk better, a thing which they could not do before. I was asked why I had not operated on the second knee. All the persons who have had bilateral involvement on whom I have operated on one knee have returned requesting the operation on the second knee, and I have had considerable difficulty dodging this second operation because I wanted to keep it as a means of control, so to speak. Dr. Murphy asked whether there were not further operations. I have done nothing but this simple removal of the patella, in contrast to synovectomy or other procedures, merely because I wanted to find out what would happen in these knees with just the simple excision of the patella. Dr. Key brought up the point that I had not mentioned Dr. Blodgett's work and Dr. J. E. Thompson's work. My article was too long. It is included

in the complete article. Several of these references are included but I did not have the time to mention them. Dr. Stump brought up the point about what physical effort had been made in the conservative management. I mentioned that we had done all manner of conservative procedures in the way of correcting the flexion deformities at the knee. These patients had had everything given to them, vaccines and all sorts of eradication of foci and all types of medication as well as all the physical therapy methods with different lights and heats. True, we have altered the shoes and made attempts at the correction of static deformities. These measures were beneficial to many of these patients, but really only for a temporary or a short period of time. On the other hand, these same individuals would return after varying periods of time with their same disability of their knees. These were not recent cases with minor bits of pathologic change in the knee, but they were rather extreme types of pathologic change. The period of duration was from a year and a half to sixteen years.

INCIDENCE OF ANESTHETIC EXPLOSIONS

PHILIP D. WOODBRIDGE, M.D.

BOSTON

The Committee on Anesthesia Accidents of the American Medical Association¹ stated in 1930: "Explosion is statistically today the least of the hazards of anesthesia." In comparison with such causes of surgical and anesthetic death as pneumonia, shock, hemorrhage, embolus, overdose of anesthetic and asphyxia from respiratory obstruction, the incidence of explosion is still so small that it may be classed with the rare complications.

Although statistically their importance is minute, they are of great emotional importance. The dramatic nature of the accident and of the death that may occur leads to publicity. The noise, the dramatic suddenness and the publicity all tend to produce a wave of fear, and under the emotional tension of fear it is felt that something must be done, and done quickly. The thing that is done not infrequently turns out to be quite illogical. Thus in one hospital after a nitrous oxide-ether explosion the use of ethylene was prohibited but that of all other agents and methods was permitted! Other instances of equally illogical action could be cited. The emotional response to explosion is in great contrast to the attitude toward other causes of death during or following operation. Although mortality rates from postoperative pneumonia and from surgical and anesthetic shock, which are a few hundred times the explosion rate and many more times the explosion death rate, cause some degree of concern, they are accepted with comparative calmness. Certainly any recurring cause of accidental death should be carefully investigated and, if possible, eradicated.

QUESTIONNAIRE

After the fatal cyclopropane explosion at the Lahey Clinic in October 1938,² an immediate need was felt for information to serve as a logical basis for determining future policy with regard to all inhalation anesthetics. We needed to know not how many explosions, fatal and not fatal, there had been with various

From the Department of Anesthesia, the Lahey Clinic.

2. Woodbridge, P. D.; Horton, J. W., and Connell, Karl: Prevention of Ignition of Anesthetic Gases by Static Spark. *J. A. M. A.* 113: 749-744 (Aug. 26) 1939.

gases, but the incidence of such explosions, the incidence of resultant death and the opinion of the anesthetists of this continent concerning the advantages of certain of the drugs and the advisability of continuing their use. For this purpose a questionnaire was sent to 100 physicians specializing in anesthesia in this country and in Canada. No anesthetist's name was included or avoided because he was known to have had an explosion.³ The list was compiled from four sources: anesthetists certified by the American Board of Anesthesiology, those certified by the American Society of Anesthetists, those who were known to have had long experience, and others known to be using a variety of anesthetic agents, including cyclopropane. An effort was made to obtain satisfactory geographic distribution. Eighty-seven of the 100 blanks were filled out and returned. Therefore there was little or no distortion of the statistical result through a selective factor determining failure to fill out the questionnaire. There may have been some distortion in an unknown direction from the fact that the blanks were sent only to physicians specializing in anesthesia. No attempt was made to include all reported explosions, because a representative, unbiased sampling was desired.

OPINIONS CONCERNING HAZARDS

The question was asked "In comparing cyclopropane with ethylene, do you believe cyclopropane possesses definitely greater explosion hazard? about the same

TABLE 1.—*Explosion Hazard of Cyclopropane*

	Explosion Hazard of Cyclopropane Is		
	Greater Than	Same as	Less Than
Hazard of ethylene.....	13 votes	44 votes	21 votes
Hazard of nitrous oxide-oxygen-ether (closed).....	19 votes	57 votes	7 votes
Hazard of ether (open).....	50 votes	16 votes	20 votes

hazard? or definitely less hazard?" A similar question was asked substituting for the word "ethylene" the phrase "nitrous oxide-ether (or oxygen-ether), given by the closed method"⁴ and a third question substituting "open drop ether." The results are given in table 1. The consensus is that cyclopropane, ethylene, nitrous oxide-oxygen-ether and oxygen-ether, given by the closed method, all present about the same explosion hazard and that open drop ether is safer in this respect.

COMPARATIVE ADVANTAGE OF CYCLOPROPANE

To determine whether anesthetists felt that cyclopropane was or was not superior to other anesthetics in any important respects, the following question was asked: "In regard to the ultimate welfare of the patient and the advantages to the surgeon, do you believe that cyclopropane, as contrasted to the other anesthetics that are available, offers great advantages to many patients or to a few patients, moderate advantage to many patients or to a few patients, slight advantage to many patients or to a few patients, or no advantage?" The phrasing of this permitted the anesthetist to check one or more answers. Thus he might indicate that he

considered it of great advantage to a few patients and of slight advantage to many. The replies as given in table 2 indicate a body of opinion overwhelmingly favorable to cyclopropane.

To determine how anesthetists felt with regard to the single factor of explosion hazard of cyclopropane as contrasted to its advantages, the following questions

TABLE 2.—*Advantage of Cyclopropane*

	Cyclopropane Offers	
	To Many Patients	To Few Patients
Great advantage.....	51 votes	23 votes
Moderate advantage.....	23 votes	4 votes
Slight advantage.....	3 votes	4 votes
No advantage.....	0 votes	0 votes

were asked: "Do you believe cyclopropane should be abandoned because of the explosion hazard? Do you believe cyclopropane should be abandoned for other reasons?" The results, given in table 3, are almost unanimously in favor of the continued use of cyclopropane. The number of votes cast against it is three, not five, for the two who voted against it "for other reasons" are among the three who voted against it "because of the explosion hazard." It is worthy of mention that, of these three, one had used cyclopropane but five times, another had used it "very few" times and had had one ether fire, and the third had not used it at all but had had two explosions with ether!

INCIDENCE OF EXPLOSIONS

In order to learn the frequency of explosions of various anesthetics in relation to one another and to the total number of administrations, these questions were asked: "About how many times has ether (all methods and combinations) been administered by you or under your supervision? How many explosions resulted? How many were killed by explosions? How many severely injured?" A similar set of questions was put with regard to ethylene, and another for cyclopropane. The results are shown in table 4. The replies cover about one and three-fourths million administrations of ether, one-third million of ethylene and one-fourth million of cyclopropane. The apparent explosion rates are respectively 1.73, 2.44 and 3.85 per hundred thousand administrations. The standard deviations due to

TABLE 3.—*Status of Cyclopropane*

	Should Cyclopropane be Abandoned	
	Yes	No
Because of explosibility?.....	3 votes	50 votes
Because of other reasons?.....	2 votes	76 votes

chance, shown to the right of these figures in table 4, are of such magnitude that the differences in these apparent rates are not significant. That is, the total number of explosions in these two and a third million administrations is so small that, if there were similar series covering ten or fifty or a hundred times as many explosions it might be found that the apparent rates shifted their relative positions, so that, for example, ether might have a higher rate than cyclopropane. So far as this questionnaire is concerned, it can only be

3. The one exception to this was that the Lahey Clinic data were included.

4. In the closed method there is no intentional escape of gases after the first few minutes of anesthesia. Exhaled gas passes through soda-lime or other chemical absorber to remove exhaled carbon dioxide. The method may be used for any inhalation anesthetic and is almost always used for cyclopropane.

said that all rates are very low and that they all fall in the neighborhood of two to four per hundred thousand.

In addition there were other reports in which the number of administrations was not given. These are shown in boldface in table 4. Thus there were thirteen additional explosions of ether among an unknown number of ether administrations reported by eleven anesthetists, two of ethylene by seven anesthetists, and none of cyclopropane by four anesthetists. Furthermore, twenty anesthetists stated that they had not used ethylene, and two that they had not used cyclopropane.

In these two and a third million anesthetics two people were killed by explosions. The mortality rate from explosion therefore appears to be extremely low. One of these was killed by an ether explosion, the other (the Lahey Clinic patient) by cyclopropane. These figures are so extremely low that it cannot be stated whether the mortality rate is greater for one of these drugs than for the other. In fact the figures both for apparent explosion rates and for deaths are such as to indicate that their occurrence is due to chance rather than to any important factor or factors which might function in relation to one of the drugs and not in relation to another.⁵

It may be assumed that the bulk of the ether administrations were by open drop, the ethylene by machine with constant or intermittent flow and escape or with the closed system with carbon dioxide absorption, and cyclopropane by the closed system. The open method probably increases the explosion hazard by allowing the heavy ether vapor to flow over the floor of the room toward distant sources of ignition and decreases it by using air as the diluent. The closed method probably

are considered to be equally dangerous as regards the explosion hazard. Open drop ether is considered to be safer.

In comparison to other anesthetics, cyclopropane is believed to offer moderate to great advantages to a large proportion of patients.

Among two and a third million administrations, the explosion rates of ether, ethylene and cyclopropane were all very low, and all fell in the neighborhood of from 2 to 4 per hundred thousand anesthetics. The explosion mortality rates were too low to be figured from the data available, since there were but two deaths in the two and a third million cases.

Clinical Notes, Suggestions and New Instruments

PAROXYSMAL LACRIMATION DURING EATING AS A SEQUEL OF FACIAL PALSY SYNDROME OF CROCODILE TEARS

LESTER ALLEN RUSSIN, M.D., IOWA CITY

My purpose in this report is to call attention again to an interesting condition of which only eight cases have previously been reported in the literature (Bogorad,¹ 1926, one case; Kroll,² 1929, one case; Kaminsky,³ 1929, two cases; Ford,⁴ 1933, four cases).

Essentially, the condition consists of a paroxysmal lacrimation every time the patient salivates during eating. It was called the "syndrome of the crocodile tears" by Bogorad, for the crocodile was formerly believed to weep hypocritical tears while devouring its victims. It occurs only after peripheral facial nerve palsies. It is not to be confused with lacrimation immediately after typical Bell's palsies, in which an ectropion is present permitting tears to run out of the conjunctival sac. In the following cases and those reported in the literature no ectropion is present and the tear duct puncta are patent.

The reader is referred to the article by Ford, who reviews the literature and interprets the observations.

REPORT OF CASES

CASE 1.—History.—W., a medical student aged 30, came to the receiving ward in September 1937 complaining of excessive lacrimation every time he eats certain foods. The past history revealed a vague history of a fall with a severe bruise on the head at the age of 14. As far as the patient could remember there was no period of unconsciousness or vomiting. It seems that several months later the patient noticed that, every time he ate, tears would brim over the right eye and run down the cheek. This condition has persisted until the present time. I have noticed the patient in the doctor's dining room during the lunch period. He can be seen sitting at the table holding his napkin close to his right eye, constantly dabbing away the tears. This condition, he states, is aggravated by sour, salty or bitter tasting foods. Mechanical stimulation of the mouth does not produce tearing.

Physical Examination.—The patient was well developed and well nourished. The right side of the face was obviously abnormal; the right palpebral fissure was smaller than the left. The right nasolabial fold was deeper than the left. There was no ectropion. When the patient was told to show his teeth,

TABLE 4.—Explosion Rates

	Replies	Adminis- trations	Explo- sions	Explosion Rate per 100,000	Killed	Injured
Ether.....	76 (11)	1,795,342 ?	31 (13)	1.73 ± 0.31	1	5
Ethylene.....	59 (7) (20)	326,798 ? None	8 (2)	2.44 ± 0.86	0	2
Cyclopropane....	51 (4) (2)	250,785 ? None	10 (0)	3.85 ± 1.22	1	0

decreases the hazard by confining the gases within the machine and increases it by using oxygen as a diluent. Some anesthetists, however, are in the habit of using air as the diluent for cyclopropane. If the ether had also usually been administered by the closed method with oxygen as the diluent, the results might have been different. This questionnaire throws no light on the influence of these factors.

SUMMARY

A questionnaire was sent to 100 anesthetists who had achieved recognition, and the eighty-seven replies that were received indicated the following:

Ethylene, cyclopropane and ether (given with oxygen or with oxygen and nitrous oxide in a closed system)

5. Yandell Henderson¹ quoted figures from questionnaires concerning ethylene sent by W. J. M. Scott to surgeons and by Hugh Cabot to hospitals. The former showed 163,000 administrations with eighteen explosions (rate 11.04 = 2.61 per hundred thousand) and one death; the latter 146,000 administrations with three explosions (rate 2.06 = 1.19 per hundred thousand) and number of deaths not stated. Nothing was said concerning the presence or absence of any selective factors in the method of collecting these figures which might have influenced the results.

Reported from the Receiving Ward, Cincinnati General Hospital.

3. Kaminsky, S. D.: Ueber das Syndrom der Krokodilstränen, *Deutsche Ztschr. f. Nervenhe.* 110: 151, 1929.

4. Ford, R. E.: Paroxysmal Lacrimation During Eating as a Sequel of Facial Palsy (Syndrome of Crocodile Tears); Report of Four Cases with Possible Interpretation and Comparison with Auriculotemporal Syndrome, *Arch. Neurol. & Psychiat.* 29: 1279-1288 (June) 1933.

he wrinkled his forehead and closed the right eyelid at the same time. This extension of the innervation to all portions of the facial musculature did not occur at all times. Under varying circumstances the innervation was more or less complete at different times.

Also when told to wrinkle his forehead the patient would show his teeth a little and close his right eyelid. This was done invariably. In other words, the patient could not innervate any one part of his right facial muscles without more or less innervating the total right facial musculature. The muscular tonus on the right side of the face was increased.

Chemical Tests.—Acid, salt or bitter substances produced a collection of tears in the right conjunctival sac, which would fill up and overflow, running down the right cheek. No other substances would produce this effect. Masticatory movements had no effect on the lacrimation. Substances with strong flavors had no effect. Sensation of taste was preserved on both sides of the tongue.

The cranial nerves were normal. Motor power and the sensorium were normal. Reflexes were normal. The medical examination otherwise was negative, including Wassermann, urine and blood tests.

The consulting ophthalmologist reported that the fundus was normal. The tear duct was probed and found to be normal.

Electrical tests were not done.

CASE 2.—History.—L. H., a Negro woman aged 27, suddenly noticed on Dec. 1, 1937, that her face was drawn to the right side. Three weeks later she had periods of forgetfulness which lasted several days. Then suddenly she had an attack of unconsciousness and convulsions with loss of sphincter control, and biting of the tongue. This dramatic episode followed an injection of neorarsphenamine. During the next week several more seizures occurred, one of which did not render her unconscious. When seen in the neurology clinic Jan. 13, 1938, the patient presented right facial weakness, staggering to the right side, pain on the right side of the face, and deafness in the right ear with tinnitus. There was no past history of epilepsy or convulsions as a child. However, there was a history of trauma to the head about the middle of October 1937 without loss of consciousness.

The neurologic examination revealed (1) negative eye-grounds; (2) the pupils dilated, the right fixed; (3) ptosis of the right eyelid; (4) paralysis of the seventh nerve; (5) sensation slightly diminished in the ophthalmic division of the fifth nerve; (6) definite diminution of hearing in the right ear; (7) palate going up in the midline; (8) gag reflex present on both sides; (9) motor division of the fifth nerve normal; (10) loss of taste on the right side of the tongue; (11) reflexes normal, with none abnormal; (12) sensorium unaltered except for the ophthalmic branch of the fifth nerve; (13) position sense normal; (14) no change in past pointing; (15) rapid movements unaltered.

Dr. Fabing, consultant neurologist, believed at this time that the patient had a peripheral lesion in the cerebellopontile angle or in the internal auditory meatus. The patient was admitted to the house in the neurology service for a complete work-up. Dr. C. D. Aring saw the patient in neurologic consultation and it was his impression that the patient had meningeal syphilis, basilar and vertical. Repeated Wassermann tests finally showed, on two occasions, plus 1 for cholesterinized antigen. Subsequent blood Wassermann tests were negative and all spinal punctures were negative. (In December 1934 the blood Wassermann reaction was negative. The spinal fluid Wassermann reaction was negative except for increased globulin.)

The patient was referred to the venereal clinic for antisyphilitic treatment in spite of the seronegative Wassermann reaction.

May 3, 1938 (six months had elapsed since the previous admission), the patient was seen in the receiving ward complaining of excessive lacrimation every time she ate certain kinds of foods. Salty and bitter foods caused tears to well up in the right eye and run down over the cheek.

Physical Examination.—The patient, though 27, looked fifteen years older. The right side of her face was obviously abnormal. There was a ptosis of the right eyelid, and the right palpebral fissure was smaller than the left. The right nasolabial fold was deeper than the left. There was no ectropion. Examination of the facial muscles revealed that the patient could not innervate any single muscle of the face without innervating all of them. For example, when told to show her teeth, the patient wrinkled her forehead and closed her right eye.

Chemical Tests.—Acid, salt and bitter substances produced lacrimation in the right eye and not in the left eye. Any other substances produced no effect. Masticatory movements had no effect on the lacrimation. Aromatic spirit of ammonia and other substances with strong odors did not produce any tearing.

Other Cranial Nerves.—1. The eye-grounds were normal. 2. The pupils were dilated, the right fixed. 3. Sensation was slightly diminished over the ophthalmic division of the fifth nerve. 4. There was definite diminution of hearing of the right ear. 5. The palate went up in the midline. 6. The gag reflex was present on both sides. 7. The motor division of the fifth nerve was normal. 8. There was loss of taste (?) on the right side of the tongue. 9. The superficial and deep reflexes were normal; there were no abnormal reflexes. 10. The sensorium was unaltered except for the ophthalmic branch of the fifth nerve. 11. The position sense was normal. 12. There was no change in past pointing. 13. Rapid movements were unaltered.

Medical examination was otherwise negative, including Wassermann, spinal puncture, blood and urine. Vestibular tests revealed normal vestibular responses.

The Weber test showed lateralization to the left: Air conduction was greater than bone conduction on the left. There was no air conduction on the right. Nerve deafness was present on the right. The tear duct was probed and found to be patent.

COMMENT AND SUMMARY

The probable explanation for the abnormal associated movements of the face, advanced by Spiller and cited by Ford, is that "The regenerating nerve fibers have become misdirected so that they no longer reach the muscles which they formerly supplied but are scattered at random over the face. The bundle of fibers which innervated the orbicularis oculi, for example, before the facial paralysis developed, is distributed among all the facial muscles during regeneration, and hence nerve impulses flowing along these fibers will cause a diffuse reaction." This is attested, for instance, by the fact that each time the patient tried to show his teeth he closed his eye on the affected side. Increased facial tone results because each facial muscle receives the same number of impulses as the whole facial musculature would receive under normal circumstances.

The lacrimation during salivation can be explained in a similar manner. It has been stated by competent observers that the seventh nerve also supplies secretory fibers to the lacrimal gland, by way of the sphenopalatine ganglion and the zygomaticotemporal nerve, as well as motor fibers to the face and sensory fibers to the anterior two thirds of the tongue and salivary glands. Any derangement of the seventh nerve would therefore affect all these simultaneously. It naturally follows, if the theory is correct, that when the fibers regenerated to the lacrimal gland some of the fibers destined to the salivary glands were misdirected. And some of those fibers that formerly supplied the salivary glands now supply the lacrimal gland as well.

Ford states that perhaps the reason why paroxysmal lacrimation does not occur more frequently, since facial palsies are common, is that it may occur but is not severe enough to warrant relief. Also that the lesions in the cases previously reported by Ford and others are located in an unusual site, probably proximal to the geniculate ganglion. Case 2 in this paper seems to bear out this assumption.

It is hoped more cases will appear in the literature to cast more light on this unusual and interesting phenomenon.

Children's Hospital.

Council on Pharmacy and Chemistry

STILBESTROL

PRELIMINARY REPORT OF THE COUNCIL

STILBESTROL is a name given to a recently developed synthetic estrogen—diethylstilbestrol—which is reported to be remarkably effective when administered orally. The unusual therapeutic results and the convenience of administration are conducive to widespread interest in the substance. In common with other estrogens, animal experiments indicate that stilbestrol may be carcinogenic under certain conditions. Evidence has appeared which indicates that toxic reactions are associated with the use of this substance. In this regard Dr. Eugene F. Du Bois, a former member of the Council, generously offered to submit to the Council results of an experimental investigation on stilbestrol performed by Dr. Ephraim Shorr and others, principally at Cornell University and the Rockefeller Institute for Medical Research. The results, appearing in a manuscript which was especially prepared for the purpose of publication as a Council report, indicate that in the hands of these investigators a large percentage of their patients developed toxic reactions of several sorts, including nausea, vomiting, cutaneous eruptions and possibly liver damage. The experiences with stilbestrol obtained by this group of investigators have not, however, been duplicated by some other workers. The reports of work conducted in Europe and, to a lesser degree, in this country, have indicated for the most part that the toxic reactions of stilbestrol were limited to gastrointestinal distress in from 5 to 15 per cent of the patients treated and that some of this distress disappeared on further medication. Shortly after the manuscript of Shorr et al. was received, Dr. C. L. Buxton and Dr. Earl T. Engle submitted a report to the Council on the effects of stilbestrol, which is based on observations of a few very carefully observed patients. These authors find little evidence that stilbestrol is more toxic than other estrogens.

An additional report on this substance in the form of a preliminary statement by Drs. Cyril M. MacBryde, Harold Freedman and Ellen Loeffel was also submitted to the Council. These authors obtained results similar to those of Drs. Buxton and Engle.

The Council authorized publication of the reports entitled "A Clinical Study of the Synthetic Estrogen Stilbestrol," by Drs. Shorr, Robinson and Papanicolaou; "Effects of the Therapeutic Use of Diethylstilbestrol," by Drs. Buxton and Engle, and the preliminary statement "Studies on Stilbestrol," by Drs. MacBryde, Freedman and Loeffel. In so doing, the Council wishes to point out that considerable more experimentation is necessary. It is well to await the outcome of further investigations which are being made in institutions which have facilities for proper experimentation and observation. Because the product is so potent and because the possibility of harm must be recognized, the Council is of the opinion that it should not be recognized for general use or for inclusion in New and Nonofficial Remedies at the present time and that its use by the general medical profession should not be undertaken until further studies have led to a better understanding of the proper functions of such drugs.

The Council expresses its thanks to Drs. Shorr, Robinson and Papanicolaou, to Drs. Buxton and Engle and to Drs. MacBryde, Freedman and Loeffel for their generous cooperation in making the reports available, and authorizes publication of these reports as preliminary statements on the status of Stilbestrol.

PAUL NICHOLAS LEECH, Secretary.

A CLINICAL STUDY OF THE SYNTHETIC ESTROGEN STILBESTROL

EPHRAIM SHORR, M.D.

FRANK H. ROBINSON, M.D.

AND

GEORGE N. PAPANICOLAOU, M.D.

NEW YORK

In 1938 Dodds, Goldberg, Lawson and Robinson¹ announced the synthesis of a new estrogenic agent, diethylstilbestrol (4:4-dihydroxy-alpha:beta-diethylstilbene). As can be seen from its formula,

it does not contain the phenanthrene ring system formerly thought to be necessary for estrogenic activity.

Dr. Robinson died November 22.

This study was aided by a Grant from the Josiah Macy Jr. Foundation. From the New York Hospital, the Departments of Medicine and Anatomy of the Cornell University Medical College, and the Hospital of the Rockefeller Institute for Medical Research.

This is an extract from the complete paper. Reprints of the article will contain the omitted paragraphs and particularly much of the tabular material. The photomicrographs will appear in the reprint also.

1. Dodds, E. C.; Goldberg, L.; Lawson, W., and Robinson, R.: Estrogenic Activity of Certain Synthetic Compounds, *Nature*, London **141**: 247 (Feb. 5) 1938.

It was found an extremely powerful estrogenic agent in animals, suffering little diminution in potency by the oral as compared to the parenteral route.² It reproduced the effects of the natural estrogens in animals and was about two and one-half times as active as estrone by injection. By the oral route the superiority over the natural estrogen was far greater, since the naturally occurring compounds lose a high percentage of their activity when given by mouth. In man the loss of activity of the natural estrogens given by mouth has been shown to be as much as 95 per cent, as judged by vaginal smears.³

These attributes of the new compound, its high estrogenic activity, its oral efficiency and its cheapness gave promise of a wide usefulness in human therapy. Preliminary experiments on animals had indicated that it was devoid of toxic effects.

Two groups of English investigators, working under the auspices of the Therapeutic Trials Committee of the Medical Research Council, reported very favorably on a trial of the synthetic estrogen in two series of women. Stilbestrol produced all the effects observed with natural estrogens, including the relief of the menopausal syndrome. In the group studied by Bishop, Boycott and Zuckermann⁴ some by-effects in the form of nausea and vomiting were noted in three of forty-six patients receiving stilbestrol. In the series reported by Winterton and MacGregor⁵ comprising fifty-one women, some of the patients experienced slight nausea during the treatment but in only one case was the drug poorly tolerated.

More extensive clinical studies, while confirming the estrogenic properties of the compound and the attendant relief of menopausal symptoms, have indicated a far higher percentage of unpleasant side reactions than those reported by the English investigators. Varangot⁶ found severe gastrointestinal reactions in eight of eighteen women. Ehrhardt, Kramann and Schäfer⁷ also report a large number of unpleasant side effects, which, however, they incline to attribute to overdosage (from 2 to 3 mg.).

To present a detailed review of the extensive literature on the clinical use of this compound is beyond the scope of this article. Many workers regard the side effects to be significant enough to condemn stilbestrol for human use.⁸ Others feel that they can be avoided by proper doses.⁷ Kellar and Sutherland⁹ state that the toxic effects following oral administration can be eliminated by employing the intramuscular route. This observation is in accord with the views of several workers who regard the toxic effects as due to local action on the mucous membrane of the gastrointestinal

tract. It has also been reported that with continuation of treatment the unpleasant by-effects tend to disappear.¹⁰

Equal lack of agreement is seen in the reports of toxicity studies in animals. They uniformly confirm the estrogenic activity of the compound and reveal an extraordinary similarity in action to the natural estrogens. Such widely diverse effects of the natural estrogens as the increased fat and calcium content of cock blood,¹¹ the inhibition of the response of the pigeon crop-gland to prolactin¹² and the sensitization of the infantile rabbit uterus to progesterone¹³ are imitated. But in contrast to the early indications of its harmlessness, Loeser¹⁴ noted in rats decreased appetite, epistaxis, vaginal and intestinal hemorrhages, fatty degeneration with subsequent necrosis of the liver, enlargement of the adrenals with arterial hyperemia and bleeding, and enlargement of the spleen with hemorrhagic reaction in the islands. According to Krietmair and Sieckmann¹⁵ the administration of from 0.5 to 1.0 mg. per gram to mice resulted in death in ten to sixteen days. In rats from 1.5 to 5 mg. per gram resulted in paralysis and death in an hour. Tislowitz¹⁶ observed a disturbance of the myelogenic system, and granulocytopenia and anemia in dogs receiving 5 mg. by injection for from twenty-five to fifty days. Morrell,¹⁷ on the other hand, has failed to observe any pathologic changes in the tissues of rats, rabbits and monkeys.

In the face of such conflicting reports it is obvious that much more knowledge of the properties of this compound will be needed before either condemning it for human use or making it generally available for estrogenic therapy.

EXPERIMENTAL SUBJECTS AND METHODS

The studies were carried out on forty-four women, many of whom had been previously treated with the natural estrogens estrone and estradiol benzoate. There were two cases of primary amenorrhea in young women (aged 19 and 22) in whom secondary sex characteristics and uterine growth had already been achieved by previous treatment with natural estrogens. Withdrawal bleeding had fairly regularly followed the administration, for periods of two weeks, of sufficient estrone or estradiol benzoate to induce a follicular vaginal smear. In the absence of treatment the vaginal smears were of the typical atrophic type we have already described as characteristic of this variety of amenorrhea.¹⁸ The remaining forty-two were cases of the menopausal syndrome, of which fourteen were spontaneous, three followed irradiation and twenty-five were associated with the removal of the uterus, ovaries or both.

The stilbestrol was obtained from two sources and administered orally in oil and in pill form, plain or enteric coated, and intramuscularly in oil. Occasion-

ally intramuscular injections of stilbestrol were alternated with amniotin or estradiol benzoate. During these periods the patients were kept unaware of the change in medication.

The vaginal smear method of evaluating estrogens in man, introduced by Papanicolaou and Shorr,³ was employed as the objective index of the action of stilbestrol. This method had been employed also by the English investigators, so that a comparison of results on this basis was possible. The smears were obtained at frequent intervals, usually three times weekly. In instances in which studies were made of comparative estrogenic potencies with the natural estrogens, daily smears were taken. Several vaginal biopsies were taken to compare the hypertrophy induced by stilbestrol with that following the natural estrogens. The smears were used to guide dosage and to compare the subjective response with the morphologic changes induced by the drug. We have already pointed out³ that there is no necessary correlation between the degree of symptomatic improvement and the extent of the smear change. The level of the smear change at which amelioration of symptoms takes place varies with the individual patient. With some, complete relief is obtained with slight changes in the smear; with others, a complete follicular change must be brought about. Most cases fall between these two extremes. The follicular stage represents full replacement with estrogenic hormone equivalent to "one human unit." It therefore serves as a measure of the estrogenic potency of a preparation and permits a simple and accurate comparison of the relative strength of the various members of this group of hormones. It will help in the interpretation of the data if these considerations are borne in mind.

The patients were seen at weekly intervals and an evaluation was made as to the effect of the medication on the menopausal symptoms. Side effects of the drug were made note of, the smears were read and further treatment was prescribed. From time to time hepatic function studies were carried out. Wherever possible, these studies were made before treatment was begun, at the end of the course and during a rest period. Often this could not be done, either because the patient could not spare the time out of working hours or because of unwillingness to repeat the tests because of the previous discomfort.

Two tests of liver function were employed, namely the sodium benzoate test as devised by Quick¹⁹ and the bilirubin tolerance test.²⁰ In the former test the patient is given 5.9 Gm. of sodium benzoate orally, and the total urine excreted during the next four hours is collected. This urine is concentrated and acidified, precipitating the hippuric acid. It is then filtered and the residue is washed with cold water. The hippuric acid residue is then dissolved in hot water and titrated with standard alkali. The amount of hippuric acid present is calculated and reported as grams of sodium benzoate. The normal individual excretes at least 3.4 Gm. of the 5.9 Gm. given in four hours. Since the excretion might be decreased in renal insufficiency, a urea clearance test is run simultaneously.

The bilirubin tolerance is performed by first determining the bilirubin blood level. One mg. of bilirubin per kilogram of body weight is dissolved in sterile 0.1 molar sodium carbonate and given intravenously. The

blood bilirubin level is then determined after five minutes and again after four hours. The percentage of bilirubin retention:

$$\frac{\text{Value of third—1st}}{\text{Value of second—1st}}$$

Normal retention is less than 5 per cent.

Whenever possible, the dose of stilbestrol aimed at was that which would produce, in addition to symptomatic relief, a typical follicular or "estrus" smear. In a number of patients, comparison was made of the relative potencies of stilbestrol by the oral and the intramuscular route with estrone, estradiol benzoate, estradiol propionate and ethinyl estradiol.

The data have been assembled in table form. [Tabular material will appear in the reprint.]

ANALYSIS OF RESULTS

1. *The Estrogenic Activity of Stilbestrol.*—That stilbestrol is a powerful estrogenic agent is apparent from inspection of the data assembled in table 2. The changes induced in the vaginal smear and epithelium are comparable to those brought about by the natural estrogens. Typical follicular smears resulting from both stilbestrol and estradiol benzoate administered to the same subject (case 5, menopausal castrate) are illustrated (figs. 1-5), as well as biopsies of the vaginal epithelium taken at the same time as the smears.

Of the forty-four cases treated with stilbestrol, such follicular smears were induced in eight. In seventeen others quite advanced prefollicular smears were seen. In two no changes occurred, probably as a consequence of the small amount of drug administered because of the patients' intolerance. The remaining sixteen showed intermediate changes. The correlation between the degree of smear change and the level of dosage of the synthetic estrogen bears out what we had previously observed with the natural estrogens, namely a considerable variation from patient to patient in the dose required to bring about a complete estrogenic effect. While the degree of smear change is roughly proportional to the dosage of stilbestrol, the influence of the individual sensitivity to the drug is quite apparent.

There were, however, certain differences in the smear changes induced by the natural estrogens and the synthetic one. These lay chiefly in the frequent failure of increasing doses of stilbestrol to bring about progressive changes in the smear picture (cases 6, 8, 26, 27, 28, 33, 35, 37, 39, 40, 41, 42, 43). Indeed, in several instances (cases 14, 15, 29, 30) actual regressions took place during the administration of the same or even higher doses.

This phenomenon may signify the acquisition by the body of some means of dealing with the compound so as to render it less active. This suggestion is based in part on evidence from perfusion experiments that the liver is capable of removing large amounts of natural estrogen from the circulation. The loss of about 95 per cent of the activity of the natural estrogens estrone and estradiol, which we have noted in the human being, finds a reasonable explanation in these experiments, since the estrogens would reach the liver immediately after absorption from the intestinal tract, presenting an opportunity for partial inactivation before entering the general circulation. The initial absence of a similar mechanism for dealing with the synthetic estrogen may be responsible for the fact that this compound loses little of its potency when taken orally. The subsequent diminution in oral efficiency in the cases cited might be due to the development, after a time, of some such mechanism for the inactivation of the compound.

In addition to the vaginal smear changes, evidence for the estrogenic activity of stilbestrol is furnished by the several cases of withdrawal bleeding in our series. Bleeding after cessation of therapy took place not only in the menopausal group but also in the two cases of primary amenorrhea studied. In case 1, withdrawal bleeding, quite scanty in amount, and of from two to three days' duration, followed two of the three courses of stilbestrol. In case 2, bleedings of from three to five days' duration followed in each of two cases. Both young women had been treated over a long period with natural estrogens, with the regular appearance of bleeding of about the same duration and character on cessation of treatment.

In contrast with the natural estrogens estrone and estradiol, stilbestrol loses little of its activity by mouth. Equivalent smear changes were induced, orally, by from one to two times the amount administered intramuscularly as compared with from fifteen to twenty times the amounts of natural estrogens required orally. Stilbestrol, however, suffers by comparison with ethinyl estradiol, the oral activity of which in the three cases studied was four and a half, seven and twenty times as great. The lower figures are probably the more accurate ones. Unfortunately, the unpleasant gastrointestinal reactions to this preparation make prolonged studies rarely possible. The greater potency of ethinyl estradiol as compared with stilbestrol in the human subjects contrasts with the animal assays,²¹ which found stilbestrol three times as active. This discrepancy indicates the necessity for human assay studies. A comparison of the oral activity of estrone and stilbestrol in one case showed the latter to be about six times as active.

By the intramuscular route, estradiol benzoate would appear to be more active than stilbestrol. One mg. of estradiol benzoate is equivalent to 6,000 rat units. On the basis of the three cases studied, its estrogenic activity would appear to be from three to four times as great as stilbestrol by injection. With respect to estrone by the same route, 1 mg. of stilbestrol brings about smear changes equivalent to about 2,500 rat units, or 1.7 mg.

From these experiments it becomes apparent that the chief advantage of the synthetic estrogen lies in its greater immunity to destruction by the oral route than the natural estrogens. This highly desirable property, combined with its low cost, would make it highly advantageous for human use were it not accompanied by very unpleasant side effects, the toxic nature of which may be suspected.

2. *The Subjective Effects of Stilbestrol.*—There is general agreement that stilbestrol, in addition to paralleling the biologic effects of the natural estrogens, is capable of ameliorating the subjective symptoms of the menopause. The results of the treatment of forty-two women with the menopausal syndrome have been condensed in table 3 from the data detailed in table 1. Except in four cases (cases 11, 22, 28, 36), in which insufficient treatment was given because of intolerance to the drug, the medication was associated with from partial to complete amelioration of the usual menopausal symptoms, the flush, headache, depression, and so on. In most instances the degree of relief experienced corresponded quite well with the extent of the vaginal smear change. However, it was often difficult to evaluate the effect of the drug on symptoms other

21. Emmens, C. W.: *J. Physiol.* 94: 22P (Dec.) 1933, quoted by Dodds, E. C.: *Stilbestrol*, *Practitioner* 142: 309 (March) 1933.

than the flush because of the frequency with which the medication was accompanied by unpleasant side effects. Even in the absence of definite discomfort, many patients were struck with the marked improvement in well-being which followed the substitution of the natural for the synthetic estrogen. This change may have been due to relief from an ill definable discomfort produced by stilbestrol rather than to a qualitative difference in its action on the menopausal symptoms as compared with the natural estrogens.

No such agreement exists as to the incidence and significance of the side or "toxic" effects resulting from the use of stilbestrol. Bishop, Boycott and Zuckermann report transitory nausea in one and vomiting in two of forty-six cases studied and express the opinion that these effects should not be considered a contraindication to the use of this preparation as an estrogenic agent. Winterton and MacGregor, treating fifty-one cases, reported slight nausea in six, which disappeared shortly despite continuation of the drug by mouth. One patient experienced slight nausea after injection, and one tolerated both forms of treatment badly. Kellar and Sutherland found the nausea by the oral route transitory and state that it could be eliminated by changing to the intramuscular route. On the other hand, Varangot noted severe gastrointestinal symptoms in eight of eighteen women, and Loeser in six of fifteen. Other workers cited also stress the high incidence of gastrointestinal symptoms.

Our results have been compiled in table 1 and condensed in table 4. Of the forty-four cases treated, toxic symptoms were absent or trivial in only nine, comprising 20 per cent of the cases. In fourteen cases (32 per cent) the drug had to be stopped because the symptoms were intolerable. In twenty-one cases (48 per cent) the drug could be continued despite the discomfort, either because of the coincidental relief of menopausal symptoms or because the patient was unaware of the connection of the medication with the symptoms. Toxic side effects, therefore, occurred in 80 per cent of the cases. The relative incidence of the different symptoms is shown in table 4.

The nausea was of all degrees of intensity, sometimes constant, sometimes occurring in waves. Vomiting either was frank or took the form of regurgitation of a clear, sweetish watery fluid. One patient (23) regurgitated moderate quantities of fluid six times during a twenty minute interview. The abdominal distress varied from uncomfortable distention after meals, epigastric pain and cramps to an intense searing sensation "as if there were a burning fluid moving about in the intestine." There was one case of severe bloody diarrhea (case 9).

Lassitude of varying intensity occurred in thirty-two cases (72 per cent). While frequently most noticed after meals in the form of an uncontrollable drowsiness and lethargy, it was occasionally present throughout the day. Some patients said that they felt as if they had been drugged. A peculiar restlessness sometimes accompanied the lassitude, which made it very difficult to relax and give way to sleep.

There were eight skin rashes noted. One (case 33) consisted of extensive areas of diffuse brawny erythema, hot to the touch, involving the back of both upper arms, and the front of the thighs just above the knees. It disappeared within two days of stopping the medication. Another (case 23) took the form of an itchy papular eruption involving the neck, shoulders and upper part of the back. The remainder were less

extensive and consisted of small macular erythematous patches associated with considerable pruritus.

The one toxic psychotic reaction in this series is of particular interest. During the second week of treatment, while the patient was receiving 2 mg. daily by mouth, her husband called the clinic to say that his wife was behaving queerly. She was seen by Dr. George Henry, of the psychiatric division, to whom we are indebted for the following summary:

The patient is tense and somewhat apprehensive and presents spasmodic coarse tremors of various parts of her body. She claims she has great difficulty in controlling herself. She says "Yesterday I cracked up. I get that vague feeling in my head and then I go haywire. I feel disconnected (lower abdomen) as though my legs didn't belong to me—only at times. Yesterday I was laughing and crying. A week ago after a neighbor told me about the Germans, I wanted to stick a knife in myself." She had an impulse to break the window and use the glass to make vaginal smears. After talking with the physician she felt more calm.

The impression was of acute, mildly delirious reaction in an emotionally unstable person. Present medication should be discontinued.

TABLE 4.—*Subjective Effects Following Administration of Stilbestrol*

(Menopausal syndrome = 42 cases)
(Primary amenorrhea = 2 cases)

Extent of Effect	Relief of Menopausal Symptoms	Toxic or Side Effects					Miscellaneous
		Nausea	Vomiting	Abdominal Distress	Diarrhea	Lassitude

++	5	11	5	14	3	12	Vertigo = 6
+++	14	12	3	6	0	16	Marked thirst = 1
++++	14	8	3	0	1	0	Paresthesias = 2
Toxic reactions							
Number.....		37	14	31	7	32	
Percentage...		84	32	70	16	72	

It was three weeks after treatment was stopped before the symptoms had disappeared completely.

Finally there were six cases of vertigo, two paresthesias (cases 3 and 12), and one patient who complained of intense thirst (patient 13) of a few days' duration. One of Loeser's patients also complained of "unquenchable" thirst after an injection of 2 mg. of stilbestrol.

Several of the authors cited describe the side effects as generally of a transitory character, the patients acquiring a tolerance with continued administration of the drug. Such was not our experience, in the main, with this group of patients. While this is occasionally seen (cases 13, 14, 15, 18, 30), as a rule the symptoms persisted throughout treatment in one form or another. They sometimes disappeared temporarily to recur suddenly, without there having been any change in dosage (cases 4, 27). A second course of treatment was tolerated just as poorly as the first (cases 3, 4, 7, 9, 14, 16, 23, 29, 35, 41, 42). There would appear to be little support for the suggestion that one may anticipate the development of a tolerance for the drug.

The suggestion has also been advanced that the side effects of stilbestrol are due to local irritation of the gastric and intestinal mucosa. This concept is contradicted by the large number of severe reactions encountered when the drug was given intramuscularly. This

was particularly striking in cases 9, 16, 22 and 23 when without the knowledge of the patient single injections of stilbestrol were given at intervals during a course of treatment with amniotin (estrone). In these cases each injection of the synthetic estrogen was followed within two or three hours by severe toxic reactions.

Finally, the side effects cannot be correlated with the dose employed in the sense that there is a critical level, e. g. 2 mg. as has been suggested, below which they do not occur. They may be present with doses of 0.5 mg. and absent when as much as 5 mg. is given (cases 9, 18 and 42).

31	4	4	3.0
33	77	35	21	3.6

From the character of the side effects, their induction by injection and the occurrence of nervous and cutaneous reactions in addition to the gastrointestinal discomfort, it would appear justifiable to regard them as largely central in origin. Local irritation of the gastric and intestinal mucosae may be a contributory factor but is not essential to the production of the side effects.

3. The Effect of Stilbestrol on Hepatic Function.—The results in the control series showed that the benzoate excretion was within normal limits in only three of nine cases, and the bilirubin tolerance test was normal in one of nine cases. Following stilbestrol administration in two (cases 27, 37) of six cases in this

group, the bilirubin retention progressively increased without a significant change in the benzoate excretion. In cases 38 and 39 the bilirubin retention increased while the benzoate excretion improved. In case 44 the bilirubin retention decreased and the benzoate excretion decreased.

Normal results for bilirubin retention and sodium benzoate excretion were obtained following stilbestrol administration in cases 26 and 30, and in case 34 even after 200 mg. was given over a seventy-eight day period. In case 6 there were both a normal bilirubin retention and sodium benzoate at the end of the course of 39 mg. in twenty-six days, and after the discontinuance of stilbestrol for fifty-one days.

In the group of ten cases (5, 7, 14, 20, 29, 41, 42, 15, 18 and 36) in which the first test was performed at the end of the stated course of stilbestrol, the bilirubin tolerance and sodium benzoate excretion test were both abnormal in three cases (5, 8 and 20); the bilirubin tolerance alone was abnormal in two cases (15 and 29); the sodium benzoate alone was abnormal in three cases (7, 18 and 41). No further stilbestrol was administered to these patients, and retests after a few weeks to months showed a variable trend, as exemplified by the fact that in three cases (14, 20 and 29) both tests showed decreased liver function and in two cases (5 and 42) the results in one test showed improvement, whereas the other showed a decrease in function and in three instances (15, 18 and 36) both tests showed improvement.

Those done during the administration of stilbestrol, as in cases 35 and 40, were equivocal. In the former the bilirubin retention increased as administration was continued and the sodium benzoate excretion tended to improve; in the latter the sodium benzoate excretion showed a rather marked improvement and the bilirubin retention did not change significantly.

The high incidence of abnormal results in the control group and the variable response in the stilbestrol-treated group prevent any conclusion at this time.

COMMENT AND SUMMARY

In this study an attempt has been made to evaluate the synthetic estrogen stilbestrol from the standpoint of its estrogenic activity, its influence on subjective symptoms of the menopause and its safety as a therapeutic agent for the human being.

Its estrogenic activity in the human being would appear to be definitely established not only on the basis of its ability to induce a follicular or estrous type of vaginal smear, vaginal cornification and withdrawal bleeding but also by evidence from other studies which have shown that endometrial hyperplasia, proliferation of the mammary epithelium and inhibition of lactation followed its use.

We have ventured to speculate on the significance of the oral immunity enjoyed by the synthetic estrogen. Two experimental observations seem pertinent to this phenomenon. The first of these is the very low recoveries of natural estrogens after injection into experimental animals. The second is the demonstration, by perfusion experiments, that the liver is capable of quickly removing large amounts of natural estrogens from the circulating blood. These observations point to the existence of some mechanism predominantly in the liver by which these hormones can be inactivated or degraded to a form with lower potency. Some such mechanism would explain the loss of activity of the

estrogens, such as estrone and estradiol, and the immaturity of estril which is believed to be a degradation form with a much lower potency than the former compounds. By mouth, these estrogens would reach the liver before getting into the peripheral circulation, offering a better opportunity for inactivation than when given by injection. The purpose of a mechanism for preventing the accumulation of the more potent estrogens in the body is as obscure as our knowledge of what the effects of such accumulations would be. If this mechanism has a homeostatic purpose, its inability to cope with the potent synthetic estrogens stilbestrol and ethinyl estradiol might not be devoid of danger. It is of interest, in this connection, that both these chemically unrelated substances should be extremely active by mouth and produce the same type of toxic side effects. May we be witnessing here that type of reaction which would result from the unchecked accumulation of highly active natural estrogens in the circulation? The reason for the existence of a mechanism for inactivation would then be apparent. It would be ironical if any gain in oral potency could be made only at the expense of the normal protective mechanisms of the body.

These studies are in accord with others cited as to the ability of stilbestrol to abolish the subjective symptoms of the menopause. Some reservations were expressed, though not very strongly, as to whether the relief induced by the synthetic estrogen was qualitatively as good as that experienced with the natural ones. It seemed more likely that the differences reported were due to the freedom from side effects with the latter preparations.

A variety of toxic effects were observed. A number of these, such as nausea, vomiting, abdominal distress, anorexia and diarrhea, were associated with the gastrointestinal tract and have been reported by other workers. They were frequently severe enough to alarm not only the patients but also the investigators. In addition to these, lassitude was a common complaint, occasionally profound enough to resemble the effect of a hypnotic. One effect, of the nature of a toxic psychotic reaction, was noted, as well as two instances of paresthesia. There was one episode of marked thirst, similar to a case reported elsewhere, and finally eight cutaneous rashes, a type of reaction not previously observed. The diversity of these effects argues for their central origin as against the suggestion that the toxic effects are due to local irritation of the gastrointestinal tract. Local irritation may play a contributory role, but all the symptoms can be induced by injection.

The high incidence of these toxic effects in our series is striking. Of forty-four cases treated, they were absent or trivial in only nine, or 20 per cent. How to reconcile the occurrence of symptoms in the remaining 80 per cent with the extremely low incidence reported by several groups of workers is not clear. In one series, that reported by Bishop, Boycott and Zuckermann,²² the low dosage and short periods of treatment frequently employed may partly account for the low incidence (7 per cent) of toxic effects. Of twenty-seven courses of treatment given by these workers to fifteen menopausal women, the daily oral dose in twelve was 0.1 mg., in seven more 1 mg. for from four to fourteen (in one case twenty-eight) days. During sixteen of these twenty-seven courses, the subjective improvement was nil. Of nine smears examined, three were consid-

ered estrous, three showed no change and three were improved, two only slightly. Of eighteen cases of amenorrhea, nine failed to have withdrawal bleeding. If the criteria of induction of follicular smears and symptomatic relief are considered a proper standard, an appreciable number of patients in this series would appear to have been undertreated. These comments are not meant as a criticism of the commendable caution exercised in the first studies of a new and potent drug but are an attempt to reconcile the discrepancies between the two studies.

The obverse question arises as to whether the patients in our series received overdoses of the drug. We felt that a fair test of the therapeutic safety of stilbestrol would consist in freedom from unpleasant reactions when amounts were taken sufficient to induce an estrous smear and complete symptomatic relief. Once these objectives were attained, the level of dosage was not raised (except inadvertently in one case, 34). The higher doses used in this study were a consequence of our adherence to these criteria and cannot be considered excessive in terms of the usual standards for the evaluation of therapeutic agents.

There appeared to be no justification for the view that the side effects could be avoided by the choice of the intramuscular route or that a tolerance to the drug could be expected to develop in most cases with its continued use.

One of the main points at issue is whether the side effects are to be regarded as unpleasant but otherwise innocuous concomitants of the action of the drug or whether they are expressions of underlying damage and hence contraindications to its use. According to the first interpretation, stilbestrol would represent a therapeutic agent suitable for restricted use by patients who are free from its side effects or willing to tolerate them and for whom expense is a major consideration, natural estrogens being available. The second view would regard the drug as unsuited for human use in its present form, interpreting the symptoms as threshold phenomena the absence of which would not necessarily preclude the presence of organic or functional damage.

Our studies of hepatic function, using bilirubin retention and hippuric acid formation as indexes, are inconclusive in that they fail to show uniform impairment in all cases in which stilbestrol was administered. Liver function tests, probably because of the large reserve of this organ, are not very sensitive to small amounts of damage. Much more work along these lines will be necessary to establish this point, and such studies are in progress.

A consideration of the evidence furnished by this as well as other studies cited forces us to the conclusion that stilbestrol in its present form is not suitable for use in the human being. Whatever doubts may exist as to the nature of the side effects produced, it would be safer to confine the drug to experimental use for the present and until the significance of the side effects is better understood. The several advantages of the drug lead us to hope that the chemist will eventually be able to modify its structure so as to retain its favorable and eliminate its unfavorable properties.

CONCLUSIONS

1. Stilbestrol is actively estrogenic in the human being, capable of inducing follicular smears, vaginal cornification and withdrawal bleeding in amenorrhea and the menopause.

²² Bishop, Boycott and Zuckermann.⁴ Winterton and MacGregor.⁵ Kellar and Sutherland.⁹

2. Less active than estradiol benzoate parenterally, stilbestrol is more efficient than the natural estrogens by mouth, losing but one half or less of its activity by this route. It is, however, less active than ethinyl estradiol by mouth. The oral estrogenic unit for the human being lies between 2 and 4 mg.

3. Stilbestrol is capable of relieving the subjective symptoms of the menopause.

4. In a series of forty-four cases treated, its use was associated in thirty-five (80 per cent) with toxic symptoms in the form of nausea, vomiting, abdominal distress, anorexia, diarrhea, lassitude, paresthesias, vertigo, thirst, an acute psychotic reaction and cutaneous rashes.

5. The toxic effects are largely central in origin, following injection as well as oral administration.

6. There is no relation between the size of the dose and the development of toxic reactions.

7. There is no evidence of an acquired tolerance to the drug.

8. Until the nature of the side effects of stilbestrol are understood, its use in the human being should be confined to experimental studies by qualified investigators.

EFFECTS OF THE THERAPEUTIC USE OF DIETHYLSTILBESTROL

C. L. BUXTON, M.D.

AND

EARL T. ENGLE, Ph.D.

NEW YORK

Diethylstilbestrol is a synthetic estrogen, the chemical and estrogenic properties of which were reported by Dodds, Lawson and Noble.¹ Extensive animal experimentation since has shown it to have more pronounced estrogenic effects when given by mouth than the naturally occurring estrogens, even when the latter are injected intramuscularly.

Guldberg² first reported the clinical use of stilbestrol in the case of a young castrate in whom he produced what he considered actual menstruation by stilbestrol and progesterone injection. Since then stilbestrol has been extensively used clinically in England and elsewhere with excellent therapeutic results in cases in which estrogen therapy is indicated.

Winterton and MacGregor³ and Kellar and Sutherland⁴ reported the frequent occurrence of nausea and vomiting following the administration of stilbestrol and that has been one of the main objections to its use. The possibility that the substance may have further toxic effects on the liver, kidney or hematopoietic system has led to the investigation of seventeen cases in which varying doses of stilbestrol were administered.

In these cases the following diagnostic procedures were carried out: complete blood counts, including

platelets, urinalysis, serum protein partition, icteric index and the van den Bergh reaction.

Eleven of these patients were being treated for menopause symptoms, four for senile vaginitis, one for ovarian insufficiency and one for secondary amenorrhea. The cases were unselected except as follows: All menopause patients were first given a therapeutic trial on small doses of phenobarbital. Only those who did not respond to phenobarbital treatments received stilbestrol. No persons were treated who had a family history of mammary carcinoma.

The carcinogenic aspects of naturally occurring estrogens when injected into mice of a carcinoma strain is well known. Geschickter⁵ has reported mammary carcinoma in normal rats not only with naturally occurring estrogens but also with stilbestrol.

The dosage of stilbestrol varied greatly, some patients receiving as little as 1 mg. a day for one week and others as much as 30 mg. a day for from fourteen to twenty-one days. One patient received 1,320 mg. over a period of four months. Improvement of symptoms had no relationship to the amount of medication given, 1 mg. a day having been found sufficient in some cases whereas as much as 30 mg. a day for twenty-days was of no help in others.

Improvement of symptoms in menopause patients was judged entirely on a reduction or cessation of hot flushes. Patients kept a daily written record of the number of flushes in twenty-four hours. Two had no change, four had a reduction of more than half of the previous number and five reported entire disappearance of the hot flushes.

Patients with kraurosis vulvae, leukoplakia and senile vaginitis have been grouped under the latter heading for the sake of convenience. They received stilbestrol in the form of wool fat ointment. All have reported relief of symptoms, and the appearance of the local lesions has improved.

The patient with ovarian insufficiency complained of profuse irregular menstruation accompanied by headache and severe depression following a unilateral salpingo-oophorectomy. Following stilbestrol treatment her menstruation became normal and the other symptoms were relieved.

The patient with secondary amenorrhea is a 34 year old woman who had not menstruated for two years. Basal metabolism and other laboratory tests were normal. Stilbestrol was given for twenty-five days, and five days following this treatment the patient had a six day period of bleeding. This procedure has been repeated for three months with the same result. At the beginning of treatment the uterus was about 5 cm. in length and the uterine cavity so small that at the time of biopsy it would admit only the smallest type of curet. No endometrium was recovered. During the stilbestrol treatment the uterus has grown to normal size and the endometrium at biopsy shows normal proliferative endometrium, with an unusual amount of mitotic activity.

Nausea and occasional vomiting occurred in four of the seventeen cases. This proportion is smaller than that reported in other series, possibly because with a few exceptions the medication was placed in gelatin capsules. The occurrence of nausea and vomiting had no relationship to the amount of drug used. The vomiting was severe enough in one case to necessitate cessation of treatment. Otherwise it was transitory.

Dizziness was mentioned in two cases but this symptom is difficult to evaluate because of its frequent occurrence without medication during the menopause.

One patient (16) with severe nausea and vomiting developed albuminuria and casts during the course of treatment. Her urine had been negative when examined several months before stilbestrol treatment, and although her other tests, including blood chemistry, were negative, it is possible that this evidence of toxicity may be attributed to stilbestrol.

the possible toxic hepatic effects of medications, the results are not considered in the conclusion of this series. None of the three patients mentioned showed toxic reactions clinically, and other generally accepted laboratory tests for liver damage were negative.

CONCLUSION

Although this series is not sufficiently large to permit a therapeutic evaluation of stilbestrol, the investigation of the possible toxic reactions of the substance has been

Results of Treatment

Case No.	Age	Diagnosis	Treatment	New Symptoms Following Treatment	Time of Laboratory Test	Result	Result of Treatment
1	45	Menopause	1 mg. daily 2 weeks	None	Immediately after treatment	Negative	Excellent
2	32	Surgical menopause	10 mg. daily 2 weeks	Weak; occasionally dizzy	Immediately after treatment	Negative	Excellent
3	32	Ovarian insufficiency	20 mg. daily 2 weeks	None	One month after treatment	Negative	Excellent
4	65	Senile vaginitis	10 mg. salve daily	None	Excellent
5	58	Senile vaginitis	2 mg. salve daily	None	One and two months after treatment	Negative	Excellent
6	40	Menopause	30 mg. daily 27 days	None	Six days after treatment	PSP 50%, albumin +, occasional casts	Poor
7	44	Menopause	30 mg. daily 2 weeks 10 mg. daily 1 week 1 month later 3 mg. daily 2 weeks 1 month later	Occasionally dizzy	Immediately after second treatment Immediately after third treatment	Negative	Excellent
8	43	Senile vaginitis	3 mg. ointment daily 2 weeks	None	Immediately after treatment	Negative	Excellent
9	41	Menopause	5 mg. daily 2 weeks then 1 (S) mg. daily	Nausea, vomiting once after treatment	Immediately after treatment	Negative	Fair
10	31	Menopause	10 mg. daily 2 weeks 10 mg. daily 1 week 1 week later 20 mg. daily 1 week later	Sore nipples	Immediately after first treatment Immediately after second treatment Immediately after third treatment Four months after last treatment	Negative Negative Negative	Poor
11	50	Menopause	3 mg. daily 1 week 2 mg. daily 5 weeks	Nausea	Immediately after first treatment Immediately after second treatment Ten days after second treatment	Negative Negative Negative	Excellent
12	31	Secondary amenorrhea	30 mg. daily 25 days 10 mg. daily 37 days	None	Immediately after first treatment Immediately after second treatment Three months after second treatment	Negative Negative	Excellent
13	60	Senile vaginitis	10 mg. daily 1 week, salve 3 mg. daily 3 weeks	None	Immediately after first treatment Immediately after second treatment	Negative	Good
14	43	Menopause	10 mg. daily 1 week	Nausea	Immediately after first treatment	Negative	Fair
15	45	Radium menopause	5 mg. (S) 1 day 1 mg. daily 20 days	None	Immediately after first treatment	Negative	Excellent
16	53	Radium menopause	5 mg. (S) 1 day 1 mg. daily 22 days	Nausea; vomiting	Immediately after first treatment	Albumin in urine 5%, occasional coarse and granular casts	Fair
17	45	Radium menopause	1 mg. (S) daily 25 days	None	Immediately after first treatment	Negative	Fair

All treatments except those marked with S were given in gelatin capsules.

* This patient complained of hypertensive cardiovascular disease and syphilis. The primary manifestations were present before treatment began; consequently these were not attributed to stilbestrol.

The Hanger cephalin flocculation test⁶ has also been carried out in a routine way on all patients. This is a new method being developed for determination of the degree of irritation of liver parenchyma. It is used as a differential diagnostic factor in the diagnosis of hepatitis. Three patients in this series have shown slight reactions to this test, indicating possible irritation of the hepatic parenchyma. As the significance of positive reactions to this test has not as yet been subjected to extensive clinical trial, especially with regard to

sufficiently prolonged and intensive to justify conclusions concerning its toxic effects. The shortest period of clinical observation following treatment has been one month; most patients have been followed for from two to three months and several for six months. Laboratory investigation included complete blood counts, including platelets, urinalysis, serum protein partition, icteric index and van den Bergh reaction. As far as can be ascertained from these laboratory studies, no evidence of toxicity can be attributed to this estrogen in sixteen of seventeen cases treated. Toxicity possibly attributed to this substance was observed in one patient with positive urinary manifestations. There has been no evidence of allergic or urticarial phenomena.

6. Hanger, F. M.: Serological Differentiation of Obstruction from Hepatogenous Jaundice by Flocculation of Cephalin-Cholesterol Emulsions, *J. Clin. Investigation* **18**: 261 (May) 1939; Flocculation of Cephalin-Cholesterol Emulsions by Pathological Sera, *Tr. A. Am. Physicians* **33**: 148, 1938.

The therapeutic results coincide with those reported in larger series. It is evident that this oral estrogen is at least as effective, in ameliorating the symptoms attributed to estrogen deficiency as other therapy by injection and is much more convenient for the patient. The nausea and vomiting is not thought to be a contraindication to the use of stilbestrol. These symptoms may be partially avoided by the use of gelatin capsules.

It should be borne in mind by the clinician that stilbestrol and the naturally occurring estrogens—estrone, estradiol and others—are not innocuous substances but act on various organs and functions of the body not intimately related to the gonads. The actions of estrogens in any or all species of animals, in causing squamous cell metaplasia of both genital and extra-genital tissues, of a direct effect on the anterior pituitary gland and other less definite but alleged effects have not been as yet clearly demonstrated in the human being. However, the observed effects in women and the abundance of data on progressive effects in animals should raise a reasonable doubt in the mind of the clinician that these substances may be given with impunity.

In particular, as stated, patients with a family history of carcinoma should not be given extensive courses of estrogenic therapy.

It appears evident that, with so potent a chemical easily available and widely used, one of the tasks confronting the clinician is to clarify the indications for estrogenic treatment and to watch for latent posttherapeutic results.

STUDIES ON STILBESTROL

PRELIMINARY STATEMENT

CYRIL M. MacBRYDE, M.D.

HAROLD FREEDMAN, M.D.

AND

ELLEN LOEFFEL, M.D.

ST. LOUIS

At the request of Dr. Barr, we are making this preliminary report to the Council.

Beginning in March 1939 we undertook studies of the new synthetic estrogen, diethylstilbestrol. We have studied thirty-seven patients in all, twelve of whom had had both ovaries removed, five part but not all of the ovarian tissue removed, five patients with marked hypogonadism and amenorrhea, and fifteen patients with severe symptoms of spontaneous menopause.

We have found diethylstilbestrol to be very actively estrogenic when given orally, as well as when administered by injection. The symptoms of hypogonadism have been relieved and there have been marked estrous changes in the vaginal smears and endometrial biopsies. Considerable breast growth has been produced and withdrawal bleeding can be produced almost at will. The doses necessary to produce these effects ranged from 0.1 mg. to 5 mg. by mouth or by injection daily.

We have not found the very high incidence of toxic effects reported by some observers. Nausea occurred in eight cases, or approximately 21 per cent of our series. Vomiting occurred in three cases after large doses but ceased when the dose was reduced. To two patients the preparation has been administered in daily doses of 5 mg. by injection for six months without any subjective or objective evidences of toxicity. The aver-

age dose employed has been 1 mg. by mouth or by injection daily. No cutaneous reactions were observed. There were no changes noted on urine examination. Complete blood studies conducted in all cases in which large amounts were administered over long periods have failed to reveal any change in the red blood cells, white blood cells, platelets or hemoglobin content. Repeated tests of liver function performed on the nine patients who received the largest doses and were treated for the longest periods failed to reveal evidence of diminished hepatic function. The liver function tests employed were estimation of the icterus index, bromsulphalein excretion, hippuric acid synthesis, galactose tolerance tests, and blood prothrombin estimations.

Animal studies that we have conducted at the same time have shown that with very large doses thrombocytopenia and purpuric manifestations can be produced. Animals receiving from two to ten times the therapeutic dose as computed by body weight have as yet failed to show any toxic manifestations.

In none of the patients treated has it been necessary to withdraw the preparation because of toxic manifestations. Nausea was produced more easily by oral treatment but occurred also after injections. Changing from parenteral to oral therapy or reducing the size of the dose has always caused disappearance of the nausea in our cases.

Our data are now almost completely assembled, and a full report will be published in the near future.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LERCIE, Secretary.

GASTRIC MUCIN.—The fraction precipitated by approximately 60 per cent alcohol from the supernatant liquid after pepsin-hydrochloric acid digestion of hog stomach linings.

Actions and Uses.—Gastric mucin is prepared for use in the treatment of peptic ulcers.

Dosage.—Average dose 2.5 Gm., which can be given at two hour intervals.

Gastric mucin occurs as a white to yellow powder or brownish yellow granules. It possesses a slightly salty taste and characteristic odor indicative of peptones. Both forms yield a viscous, gray, opalescent solution when triturated with water.

Dry approximately 1 Gm. of gastric mucin, accurately weighed, to constant weight at 100 C.: the loss in weight does not exceed 6 per cent.

Incinerate approximately 1 Gm. of gastric mucin, accurately weighed, in a muffle furnace at 500 C.: the ash content does not exceed 6.5 per cent.

Transfer a 10 Gm. sample of gastric mucin to a 125 cc. Erlenmeyer flask and add 100 cc. of 70 per cent ethanol (737 cc. of U. S. P. ethanol diluted to 1 liter). Stopper the flask, shake the mixture for thirty minutes and decant the supernatant liquid. Repeat this addition of alcohol and extraction for a total of six times. Measure the combined extracts and filter a portion through a dry filter paper. Evaporate 50 cc. of the filtrate to dryness, dry at 100 C. and 72 cm. of mercury to constant weight, and calculate the dry weight, *S*, in the total volume of alcohol. The mucin content, calculated as $(10-S) \times 10$, is not less than 73 per cent nor more than 90 per cent.

Determine the nitrogen content in the dried alcohol insoluble residue (described in the foregoing paragraph) by the Kjeldahl method according to Methods of Analysis of the Association of Official Agricultural Chemists, ed. 4, page 23: the nitrogen content is not less than 7.0 nor more than 9.0 per cent.

Transfer 0.1 Gm. of the dried alcohol insoluble residue as previously obtained to a 125 cc. Erlenmeyer flask and add 50 cc. of two-normal sulfuric acid. Digest on a steam bath under a reflux condenser for three hours and dilute to 100 cc. Transfer 4 cc. of this solution to 30 per mm. test tube, add 1 drop of phenolphthalein and neutralize with 30 per cent sodium hydroxide. Add 5 cc. of standard copper reagent (Twenty-five Gm. of anhydrous sodium carbonate, 20 Gm. of sodium bicarbonate and 25 Gm. of sodium potassium tartrate is dissolved in 600 cc. of distilled water; 7.5 Gm. of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ is dissolved in 100 cc. of water and introduced with constant stirring into the carbonate-tartrate solution through a funnel resting on the bottom of the container. To the solution add 5 Gm. of potassium iodide and 22 cc. of an alkaline standard normal solution of potassium biiodate (32.498 Gm. of potassium biiodate

and 83.3 cc. of normal sodium hydroxide made up to 1 liter). The resultant solution is made up to exactly 1,000 cc. and make up to 10 cc. Cover the test tube with a small beaker and suspend it in boiling water. Add 5 cc. of normal sulfuric acid and after one minute titrate with 0.005 normal sodium thiosulfate, using starch as an indicator. The sodium thiosulfate is standardized against the 0.022 normal copper sulfate-iodate reagent, 5 cc. of which should require 22.0 cc. of the thiosulfate. The difference between this control figure and the number of cubic centimeters of thiosulfate used in the determination should not be less than 8.6 nor more than 12.2 cc.; that is, not less than 25 per cent nor more than 35 per cent of reducing material, calculated as dextrose in the alcohol insoluble material.

Prepare a 2 per cent solution of gastric mucin by triturating 2 Gm. of mucin with 100 cc. of water and passing it through a 60 mesh screen. Determine the *pH* of this solution by means of a glass electrode at 25 C.; the *pH* is not below 3.7 nor above 6.5. Determine the viscosity of this solution at 25 C. within one hour by means of a 10 cc. Mohr pipet and compare it with water: the relative viscosity is not below 1.30 nor above 3.50.

Gastric Mucin-Armour.—A brand of gastric mucin-N. N. R. Manufactured by the Armour Laboratories, Chicago, by license from the Gastric Mucin Committee of Northwestern University Medical School under U. S. patent 1,829,270 (Oct. 27, 1931; expires 1949). No U. S. trademark.

Gastric Mucin Powder-Armour.
Gastric Mucin Granules-Armour.

Gastric Mucin-Stearns.—A brand of gastric mucin-N. N. R. Manufactured by Frederick Stearns & Co., Detroit, Mich., by license from the Gastric Mucin Committee of Northwestern University Medical School under U. S. patent 1,829,270 (Oct. 27, 1931; expires 1949). No U. S. trademark.

Gastric Mucin Powder-Stearns.
Gastric Mucin Granules-Stearns.

Gastric Mucin-Wilson.—A brand of gastric mucin-N. N. R. Manufactured by the Wilson Laboratories, Chicago, by license from the Gastric Mucin Committee of Northwestern University Medical School under U. S. patent 1,829,270 (Oct. 27, 1931; expires 1949). No U. S. trademark.

Gastric Mucin Powder-Wilson.
Gastric Mucin Granules-Wilson.

ASCORBIC ACID (Cevitamic Acid) (See New and Nonofficial Remedies, 1939, p. 499). The following dosage form has been accepted:

I. P. C. Ascorbic Acid Tablets: Each tablet contains not less than 0.025 Gm. of ascorbic acid, equivalent to 500 international units of vitamin C per tablet.

Prepared by the International Vitamin Corporation, New York.

THIAMIN CHLORIDE (See New and Nonofficial Remedies, 1939, p. 498). The following dosage forms have been accepted:

I. P. C. Thiamin Chloride Crystalline Tablets, 0.5 mg.: Each tablet contains 0.5 mg. of thiamin chloride, equivalent to 166 international units of vitamin B₁.

Prepared by the International Vitamin Corporation, New York. No U. S. patent or trademark.

I. P. C. Thiamin Chloride Crystalline Tablets, 1.0 mg.: Each tablet contains 1.0 mg. of thiamin chloride, equivalent to 333 international units of vitamin B₁.

Prepared by the International Vitamin Corporation, New York. No U. S. patent or trademark.

I. P. C. Thiamin Chloride Crystalline Tablets, 3.3 mg.: Each tablet contains 3.3 mg. of thiamin chloride, equivalent to 1,100 international units of vitamin B₁.

Prepared by the International Vitamin Corporation, New York. No U. S. patent or trademark.

SODIUM CITRATE 2½% W/V IN PHYSIOLOGIC SOLUTION OF SODIUM CHLORIDE IN TRANSFUSO-VAC CONTAINER-BAXTER.—A 2.5 per cent solution of sodium citrate in physiologic solution of sodium chloride contained under reduced pressure in a specially adapted bottle.

Actions and Uses.—For indirect blood transfusion. The flow of blood from the needle in the donor's vein into sterile citrate solution in an evacuated container is controlled by a simple valve. The blood is administered to the recipient by gravity flow and is completely filtered during administration.

Manufactured by Baxter Laboratories, Inc., Glenview, Ill. (American Hospital Supply Corporation, Chicago, distributor). U. S. patent 1,941,071; additional U. S. patent pending. U. S. trademark 365,142.

Sodium Citrate 2½% W/V in Physiologic Solution of Sodium Chloride in Transfuso-Vac Container, 33 cc., Baxter: Contains 2.5 per cent sodium citrate in physiologic sodium chloride solution.

Sodium Citrate 2½% W/V in Physiologic Solution of Sodium Chloride in Transfuso-Vac Container, 70 cc., Baxter: Contains 2.5 per cent sodium citrate in physiologic sodium chloride solution.

Sodium Citrate 2½% W/V in Physiologic Solution of Sodium Chloride in Transfuso-Vac Container, 105 cc., Baxter: Contains 2.5 per cent sodium citrate in physiologic sodium chloride solution.

Sodium citrate 2½% W/V in physiologic solution of sodium chloride is a clear colorless, odorless solution possessing a salty taste. It is contained under a pressure of approximately 8 cm. of mercury, in a bottle which can be equipped with an accompanying valve to regulate the inflow of liquids. The solution responds to the qualitative tests for sodium, chlorides and citrates as given in the U. S. Pharmacopeia under Sodium Citrate and Sodium Chloride respectively.

Insert the closed valve in the bottle and attach the valve outlet to a manometer; slowly open the valve; the mercury rise indicates a maximum internal pressure of 120 mm. at 25 C.

The *pH* of the solution, as determined by means of a glass electrode, should not be above 7.5 nor below 6.7. Evaporate a 25 cc. sample in a tared platinum dish to dryness on the steam bath and dry to constant weight at 120 C.; the weight of the residue is not more than 0.880 Gm. nor less than 0.800 Gm. Carefully ignite this residue until the ash is white, care being taken not to heat the dish above a dull red. Cool and transfer the dish and contents to a 250 cc. beaker; add 17.5 cc. of half-normal sulfuric acid and 30 cc. of water, and digest the mixture on the steam bath for one hour. Filter the solution, wash the residue carefully, and titrate the filtrate with tenth-normal sodium hydroxide, using methyl orange as an indicator: the calculated sodium citrate content is not more than 2.60 Gm. nor less than 2.30 Gm. per hundred cubic centimeters.

NICOTINIC ACID (See New and Nonofficial Remedies, 1939, p. 495).

Nicotinic Acid-N. Y. Q.—A brand of nicotinic acid-N. N. R. Manufactured by the New York Quinine and Chemical Works, Inc., Brooklyn, N. Y. No U. S. patent or trademark.

FERROUS SULFATE, DESICCATED.—Exsiccated Ferrous Sulfate.—Dried Ferrous Sulfate.—Exsiccated Ferrous Sulfate contains the equivalent of not less than 80 per cent of anhydrous ferrous sulfate [FeSO₄].—U. S. P. X.

Actions and Uses.—The product is generally administered in the form of pills, for the purpose of increasing the hemoglobin of the blood. It was formerly official in the U. S. P. X but was omitted from the U. S. P. XI. Its advantages over the official hydrous preparation are its physical properties (the hydrated material is difficult to capsule).

Dosage.—From 0.3 to 0.6 Gm. (5 to 10 grains) daily.

Manufactured by Lederle Laboratories, Inc., Pearl River, N. Y. No U. S. patent or trademark.

Dried Ferrous Sulfate Capsules 0.33 Gm. (5 grains): Each capsule contains approximately 0.33 Gm. (5 grains) of dried ferrous sulfate, which is equivalent to about 0.11 Gm. of metallic iron.

Desiccated ferrous sulfate occurs as an odorless, tasteless, grayish white powder. It dissolves slowly but almost completely in water and is insoluble in alcohol. When ignited, the salt rapidly darkens to a red-brown colored powder.

Place about 1 Gm. of desiccated ferrous sulfate in a stoppered graduated cylinder, add 20 cc. of recently boiled and cooled distilled water, filter the solution rapidly and divide the filtrate into four portions; to one portion add 1 cc. of potassium ferricyanide solution; a dark blue precipitate which is insoluble in hydrochloric acid but is decomposed by sodium hydroxide, results; to another portion add 1 cc. of sodium hydroxide; a greenish yellow precipitate forms which changes rapidly to green-brown and finally to brown on shaking in air; to another portion add 1 cc. of barium chloride solution; a white precipitate results insoluble in hydrochloric and nitric acids; to the last portion add five drops of lead acetate solution; a white precipitate soluble in excess ammonium acetate results.

Dry about 5 Gm. of desiccated ferrous sulfate, accurately weighed, to constant weight at 100 C.; the loss does not exceed 1 per cent. Dissolve the foregoing dried salt in about 90 cc. of water, add 10 cc. of nitric acid and boil to expel oxides of nitrogen. Pour while hot, with stirring, into a mixture of 80 cc. of water and 20 cc. of ammonium hydroxide; filter and wash the precipitate with water until the filtrate with stirring, ignites; a residue of not more than 0.1 per cent remains (alkalis and earths); neutralize another 100 cc. portion of the filtrate with glacial acetic acid and add 1 cc. in excess, followed by 2 cc. of fresh potassium ferrocyanide solution; neither a pink color nor a turbidity is produced in ten minutes (copper and zinc).

Transfer about 5 Gm. of desiccated ferrous sulfate, accurately weighed, to a 100 cc. stoppered calibrated flask, add 50 cc. of recently boiled and cooled distilled water, 2 cc. of sulfuric acid, and finally fill to the mark with water; stopper the flask tightly, allow the salt to dissolve and mix thoroughly: the resultant solution possesses a pale green color and is but slightly turbid; filter through a tared sintered-glass crucible and dry at 110 C.; the residue does not exceed 0.1 per cent. Transfer about 0.75 Gm. of desiccated ferrous sulfate, accurately weighed, to a 100 cc. Erlenmeyer flask, dissolve in 20 cc. of diluted sulfuric acid and titrate immediately with tenth-normal potassium permanganate: the content of anhydrous ferrous sulfate [FeSO₄] is not less than 80 per cent nor more than 89 per cent.

LIQUID PETROLATUM (See New and Nonofficial Remedies, 1939, p. 300).

Mead's Mineral Oil with Malt Syrup: An emulsion of white mineral oil with malt syrup. White mineral oil 50 cc., with acaia and gum tragacanth, is dispersed in malt syrup. The malt syrup is prepared by nailing a mixture containing approximately 80 per cent of barley and gum per cent of corn starch. The mixture is standardized, and 2 cc. of alcohol is added to make 100 cc. The percentage by weight composition of the emulsion is as follows: malt syrup (78 per cent solid) 54 per cent, mineral oil 38 per cent, water 5.5 per cent, alcohol 1.4 per cent, acaia 1 per cent and gum tragacanth 0.1 per cent.

SATURDAY, DECEMBER 23, 1939

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

THE PITUITARY GLAND AND WATER DIURESIS

The conception has been advanced that the kidney, under normal conditions and with respect to tubular activity in the reabsorption of water, is subject to stimulation by the antidiuretic hormone, the degree of stimulation being proportional to the amount of hormone present in the blood and, consequently, to the rate of pituitary secretion. Furthermore, the secretion of the pituitary may be governed in turn by nervous stimuli or by changes in the composition of the blood transmitted to the gland through mediation of the central nervous system. This theory of a control of urine volume by the pituitary is attractive and has been called on to explain variations in water excretion which occur under diverse circumstances, including water diuresis.

Reports conflict with regard to proof of the presence of antidiuretic hormone in body fluids in concentrations which vary with physiologic variations in urine volume.

As pointed out by Walker,¹ it seems essential to the acceptance of the theory that this proof be furnished. Because of the importance of investigations which throw light on this side of the problem, the observations of Gilman and Goodman² have attracted considerable attention and have already been discussed in *THE JOURNAL*.³ This study indicated the presence of antidiuretic substance in the urine of dehydrated rats but not in the urine of normal control animals and also not in the urine of dehydrated hypophysectomized rats. With regard to the excretion of antidiuretic principle by dehydrated rats, the observations of these workers have in general been corroborated by Bolyston and Ivy,⁴ and similar results have also been reported for cats by Ingram and his associates.⁵ The recent investigation of Walker¹ on the occurrence of antidiuretic substance in the urine, blood and cerebrospinal fluid of various animals deserves particular mention because the results obtained failed to disclose definitive support for the pituitary hormone theory of water diuresis. Although an antidiuretic potency which appeared to be peculiar to dehydrated animals could be demonstrated in rabbit blood and rat urine, prolonged experimentation indicated that the antidiuretic material in the latter was not identical with the antidiuretic fraction of pituitary secretion. Indeed it was found that alteration in the experimental conditions of the method used for detecting antidiuretic material permitted the demonstration of an antidiuretic effect in the urine of hydrated as well as dehydrated rats and also in the urine of several rats which had been completely hypophysectomized. Moreover, the presence of the pituitary gland was found to be unnecessary for the occurrence of antidiuretic substance in the urine of cats, since it was found in essentially unaltered amounts in hypophysectomized specimens in a number of cases. It is also noteworthy that the cerebrospinal fluid of pituitarectomized as well as normal dogs possessed an antidiuretic effect. Walker also studied the response of pituitarectomized animals to water administration and withdrawal; he found it to be similar to that of normal animals, indicating that in this case some mechanism other than the posterior lobe of the pituitary gland is capable of effecting alteration in the urine volume. In this connection it may be recalled that Newton and Smirk,⁶ in a study on the pituitary gland in relation to water diuresis, have reported that a natural control of this process may be present in decerebrate cats with total hypophysectomy.

Particularly in view of the results of the recent experimental study of Walker, it would appear that there is some doubt as to the origin of the antidiuretic substance which has been detected in the urine as well as

in the blood and cerebrospinal fluid of a number of animals under certain experimental conditions. The role of the pituitary in the mechanism responsible for controlling water diuresis requires additional elucidation. Because of the theoretical and practical importance of the problem of excretion of water by the kidney, further developments which throw more light on this problem will be awaited with interest.

PHYSICIAN AND PHARMACOPEIA

THE JOURNAL on previous occasions has criticized the machinery for the production of the U. S. Pharmacopeia, pointing out that the decennial convention occasionally has been controlled unduly by the pharmaceutical interests.¹ That the criticism is cogent may be confirmed easily when one refers to the proceedings of the 1930 convention. Medicine has not received its just representation because fewer physicians than pharmaceutical representatives have been appointed for the decennial convention. While it is true that each incorporated state medical association and each incorporated medical college and each medical school connected with an incorporated college or university is entitled to send three delegates to the Pharmacopeial Convention, state medical societies and medical colleges hesitate to incur the expense of sending three delegates. For that reason the Board of Trustees of the American Medical Association, the Council on Pharmacy and Chemistry and THE JOURNAL have suggested² that the evils of one-sided representation could be corrected if only one vote was recorded for an organization. The next convention meets the second Tuesday in May 1940 at Washington. Its deliberations will inaugurate any new procedures that may be possible for the better conduct of future conventions. The committee which it appoints will be the one that will largely determine the policies of the U. S. Pharmacopeia XII.

The Pharmacopeia is significant particularly because of its relation to the present Food, Drug and Cosmetic Act. The Pharmacopeia has been the book which describes the standards for many drugs and some medical appliances, such as catgut and absorbent cotton. The law provides that the Food and Drug Administration of the U. S. Department of Agriculture may enforce these standards. In its cooperation the medical profession must meet the reasonable demands set forth previously,² particularly proper representation and the determination of the therapeutic scope of the Pharmacopeia. Every state medical society should send to the convention the three delegates to which it is entitled. The selection of these delegates, such as pharmacologists or practitioners, should be along the lines laid down by THE JOURNAL ten years ago.³ A delegate need not

necessarily be a resident of the state in which the society or school is located, but he should know the policies of the group he represents. Because of an outworn provision only persons who attend the decennial convention are eligible for membership on the Revision Committee. This stipulation should be kept in mind in the selection of proper representatives.

In the 1930 convention only three state medical societies had full representation, and half of the state medical societies did not have any representatives. Medical schools did better; twelve sent three delegates each, but forty schools were represented by only seventy-one representatives instead of the 120 to which they were entitled. Other medical schools failed to send delegates. If this situation is repeated in 1940, the Pharmacopeial method of procedure may again fail to be revised to meet the difficult issues which have developed.

ESTROGEN THERAPY—A WARNING

The last ten years has seen a remarkable development in our knowledge of the endocrines. Especially great strides have been made in the therapeutic application of sex hormones, notably the estrogenic substances. Pure highly potent preparations of estrogens are being manufactured. Furthermore, biochemists are constantly striving to discover new compounds of even greater activity or to increase the efficiency of those already known. Pharmaceutical chemists are looking for better preparations which may be protected by patent. Much attention has been given to the preparation of estrogens for oral use, since the advantages of such therapy over hypodermic administration are appreciable.

Two new compounds—ethinyl estradiol and diethylstilbestrol—have been used clinically in recent months and have been shown to be as effective as the injected estrogens in moderate doses. General acceptance of these compounds has been prevented by complaints of disagreeable symptoms following their ingestion. Ethinyl estradiol induced in a considerable percentage of patients nausea, vomiting, headache and malaise. Diethylstilbestrol, however, has been prescribed, especially in England. The reports as to the toxic reactions of this substance are quite conflicting, some investigators stating that gastric distress is the only complaint, that this is experienced by from 5 to 10 per cent of the patients, and that it vanishes after a few days of administration. Others have found side reactions in greater numbers. One group of American investigators has observed as high as 80 per cent of the patients exhibiting untoward reactions, including cutaneous eruptions, psychosis, lassitude and liver damage. Apparently a thorough investigation of this compound is in order before it can be prescribed for routine therapy. In this issue of THE JOURNAL (p. 2312) will be found a statement of the Council on Pharmacy and Chemistry on the present status of stilbestrol; also three articles published under its auspices.

1. The Pharmacopeial Convention, editorial, J. A. M. A. 94:1707 (May 24) 1930.

2. The Call for the Pharmacopeial Convention of 1940, editorial, J. A. M. A. 112:1969 (May 13) 1939.

3. The Call for the Appointment of Delegates to the United States Pharmacopeial Convention, J. A. M. A. 93:939 (Sept. 28) 1929.

The conflicts in the reports on these substances and the opinions of some authorities on the possible harm from estrogen therapy should warn against long continued and indiscriminate therapeutic use of estrogens. Like numerous other therapeutic agents estrogens are effective under the proper circumstances, but there may be definite danger when they are used unscientifically. In this connection the possibility of carcinoma induced by estrogens cannot be ignored. The long continued administration of these proliferating agents to patients with a predisposition to cancer may be hazardous. The idea that estrogens are related in their activity only to sex organs should be abandoned. Other tissues of the body may react in an undesirable manner when the doses are excessive and over too long a period. This point should be firmly established, since it appears likely that in the future the medical profession may be impertuned to prescribe to patients large doses of high potency estrogens, such as stilbestrol, because of the ease of administration of these preparations.

Current Comment

TREATMENT OF PNEUMONIA

So much has been published concerning the newer methods of treating pneumonia that it is often difficult to determine what is a practical procedure. Recently, however, the Maryland State Department of Health, through its Pneumonia Control Committee, has released its recommendations to the profession. The first recommendation is that every effort be made to obtain sputum for typing at each visit, unless the type of infecting pneumococcus has already been determined. Suitable containers for collecting specimens are provided by the board and specimens should be sent to county or state laboratories as soon as obtained. Sulfapyridine therapy should be begun as soon as the diagnosis of pneumonia is made. The initial dose for an adult (any patient over 14) should be 60 grains (4 Gm.) followed by 15 grains (1 Gm.) every four hours until the temperature has been normal for forty-eight hours; thereafter 15 grains is given four times a day until resolution is well under way or the patient's temperature has been normal for four days. Finally, $7\frac{1}{2}$ grains (0.5 Gm.) is given four times a day until the patient is ready to leave bed. Directions are also given for adding salt if vomiting is present, for including sodium bicarbonate and for giving at least 4 quarts (liters) of fluid each day during which sulfapyridine is administered. Children weighing under 40 pounds (18 Kg.) are given 1 grain (0.065 Gm.) of sulfapyridine per pound of body weight as an initial dose. After this one fourth of the initial dose is given four times daily for the next four days, at the end of which time the dose is halved and continued until the temperature is normal for at least five days. The drug should be withheld from patients who have developed drug fever or rash, anemia, jaundice or leukopenia during a previous course of sulfanilamide or sulfapyridine therapy. Warning is issued to discontinue the drug immediately should such well known symptoms as anemia, leuko-

penia, hematuria, jaundice, drug fever or drug rash appear. Sulfapyridine is placed in the hands of each county health officer for free distribution when certified as necessary by the physician. The department of health through its regional laboratories and through specially trained public health nurses also provides an alternate day laboratory service of blood counts which, the committee believes, supplemented by careful clinical observations, offers a reasonable safeguard against serious toxic effects. This service is supplied free, when requested, by a public health nurse. The recommendations made by this committee not only constitute excellent medical practice but also are completely practicable and are readily adaptable to many states.

TUBERCULOSIS IN YOUNG CHILDREN

Knowledge of the pathogenesis of pulmonary tuberculosis in small children has been previously extended by some of the studies at the Lymanhurst Health Center of Minneapolis during recent years. Now Tortone and his colleagues¹ report a follow-up study of 4,328 children who received tuberculin tests on entering the clinic. Of these, 79.1 per cent had negative and 16.4 per cent had positive tuberculin reactions when first tested; in the remaining 4.5 per cent the results of the initial tuberculin test were inconclusive. The x-ray study of more than 1,700 children not sensitive to tuberculin failed to reveal lesions suggestive of tuberculosis. Of the 701 children who were sensitive to tuberculin when first tested, the initial x-ray examination disclosed no lesion in 268, calcification in 286 and pneumonic infiltrations in 155. The incidence of pneumonic infiltration interpreted as primary pulmonary tuberculosis in the acute inflammatory stage of development decreased gradually with advancing age. Of the 629 children with positive tuberculin reactions on entrance who were traced for an average period of about five years, ten had died of tuberculosis, five under 1 year of age and five between 1 year and 2. Eight of these children who died had remained in intimate contact with persons in their respective homes who were known to have open tuberculosis. The pneumonic primary infiltration found on the x-ray examinations of 146 tuberculin sensitive children who controlled and survived this form of the disease resolved spontaneously in each instance. This resolution left the lungs roentgenographically normal in 100 children and produced Ghon tubercles in forty-six. Of the 3,424 children who failed to react to tuberculin on the first test, 157 later became sensitive to tuberculin. X-ray studies made after these primary infections revealed normal lungs in ninety-one, pneumonic infiltration in seventeen and intrathoracic deposits of calcium in forty-nine. None of these children died of tuberculosis in the period during which they were followed. It may be concluded from these studies that primary tuberculosis in young children in Minneapolis tends to be a relatively benign disease and that they control and survive infection with tubercle bacilli much more often than was formerly considered possible.

ORGANIZATION SECTION

THE SMALL COMMUNITY HOSPITAL AS A TEACHING HOSPITAL

J. T. MORRISON, M.D.
NEW YORK

Why cannot a fifty-bed community hospital render a service on the firing line, as it were, of medical practice such as is rendered by a teaching hospital? The consensus is that a teaching hospital is a hospital organized for the purpose of undergraduate teaching and intern training and attached to, or administered by, a medical school. Such a hospital is thoroughly organized into medical and administrative departments, each with its own chief who directs its efforts, supervises its work and inspires its teaching activities. The staff at such a hospital naturally gives attention to the detail of clinical records in order to develop a basis for medical literature, establishes a minimum standard of diagnostic procedure as a guide for those ministering to patients, makes detailed laboratory and x-ray studies of each patient to support the clinical observations and study the effects of disease, arranges for clinical pathologic conferences or staff conferences to pool experience, and organizes seminars and journal clubs which all staff members must attend. All this is considered necessary in a teaching hospital as general opinion visualizes such an institution, in order to teach undergraduates and interns the best medical practice, the most scientific approach to the study of illness and the methods of seeking and obtaining medical information.

This conception of a teaching hospital does not fit the small rural hospital. It lays emphasis on a pyramid type of staff organization and places responsibility on the department heads for the continued study of the art and science of medicine. A resident physician in a fifty bed rural hospital recently remarked that there is so much clinical material available at the hospital that he would need at least thirty-six hours in every day in which to study it, to do the patient justice and to make it most valuable to him. His use of the two concepts clinical material and study are fundamental and a real lead in developing the teaching ideal as it applies to the small hospital. Teaching is based on the study of illness. What is there in environment causing it and how can it be most successfully diagnosed and treated? Therefore in attacking these problems a teaching hospital should be found wherever there is a patient in a hospital and wherever there are inquiring minds on the staff of physicians attending the patients. Following this ideal, staff members approaching the study and care of illness with the spirit of critical analysis of each patient should be able to make teaching material from even the so-called routine medical work they are called on to handle in their day to day hospital practice.

Since the care of the patient is medical practice and the acquisition of experience important, one of the most important steps in teaching is the pooling of the individual experience of each physician with that of others in a common fund of knowledge. In the community hospital where there are no department heads and the staff organization is horizontal, this can be done best in the hospital staff meeting, provided of

course the staff members approach their meeting with the spirit of critically analyzing and freely discussing their experience. Staff leadership in terms of individuals may be officially vested in elected chairmen and appointed committees, but staff leadership providing the stimulus for a high quality of medical work is unofficially vested in the consensus of the staff as a group. A concerted will to share experience, submerge individual personalities and establish a real give and take of critical judgment is the only sound basis for a teaching hospital. Every physician of the staff is both instructor and pupil.

Patients entering such a hospital know that under the standard of the hospital a real study of their illnesses will be made before treatment is undertaken. They know that their illnesses will receive the benefit of collective opinion of the entire staff. The staff in setting up such a standard makes each individual member responsible to the staff as a group for the maintenance of good quality of medical work. In setting this standard the staff is establishing a teaching hospital.

A staff that pools its experience in staff meeting and that sets up a minimum standard of diagnostic and therapeutic practice will quite naturally give attention to the development of another activity which, for want of a better word, is called "consultation." This might well be the informal interchange of thought and experience between staff members in their day to day hospital experience. In some hospitals the minimum standards may specify that all instances of serious illness likely to result in death or the interruption of a known, suspected or possible pregnancy shall have the benefit of written consultation with another staff member. The majority of consultations, however, are quite informal, two or more physicians of the staff viewing the patient and studying the illness as a complete entity with the added knowledge of the patient's home life in the community to assist them in reaching a conclusion. For future reference the second physician adds a note in the progress notes to indicate his observations, his line of thought and his conclusions, but the real interchange of information takes place in the corridor or the staff library. In other words, patients admitted to the hospital have the benefit of the experience of more than one of the physicians of the community. In one community hospital 25 per cent of all patients admitted last year had the benefit of written consultation as determined from the clinical records. Such a report of written consultations indicates the possibility that at least another 25 per cent of patients had the benefit of consultations which were not recorded. The hospital is a teaching hospital.

There is a considerable amount of drudgery to the preparation of a clinical record, with the result that much is omitted which is later found to be important, either in staff meeting or possibly even in the court room. The history and physical examination are important in the clinical record, but what is most important is the clinician's summary indicating his thinking in reaching his conclusion as to the disease process pres-

ent. Too frequently this is omitted in favor of a simple statement of the tentative diagnosis, making one wonder whether he might be afraid to indicate his method of arriving at the conclusion. Next most important is an accurate detailed description of the therapy used—medical, surgical, dietary or other—and the day to day record in the progress notes of the convalescence.

The hospital administration has the responsibility of building the staff library of current experience into something of value by making provision to index and file all records so that they are readily available for patients as a health record or for physicians as a study of illness. This requires the use of a nomenclature by both the hospital and the staff in order to index by disease classification. It also requires that the staff set forth the events in their hospital practice they may later want to study so that these can be indexed. Hospitals giving such attention to recording and indexing the experience of the staff are building a reference library of their own clinical material. Medical staffs using their clinical records as a basis for study are pooling their recorded experience. They are certainly teaching hospitals.

Frequently the discussion of medical records suggests to the staff a need for securing outside experience to add to their own. In such instances the staff will go to its medical library to obtain the benefit of the experience of others. A teaching hospital will therefore give considerable attention to the development of the hospital library, basing it on standard textbooks and developing it with current periodicals. But more than just buying books and periodicals is necessary to get the fullest use of the library. In one hospital the staff requests the library committee to report at each meeting on the material received in the current periodicals. With the presentation of each clinical record some report will be made of the experience of others as recorded in the current periodicals. In other hospitals there is an active journal club where each month a different phase of medical work is discussed on the basis of current and past literature. At this hospital fifteen minutes of each staff meeting is given over to the discussion of a case record reported and discussed in one of their weekly periodicals. This case record is typed off so that each staff member has a copy. In the course of the meeting each one sums up the case history in his own words and draws his conclusion.

When all have entered their comments, the final diagnosis and the comments of the attending physician are presented as well as the results of necropsy if a death occurred. These hospitals are teaching hospitals. They are adding the proved experience of medical history to their own.

The hospitals under discussion will supply as complete a service in pathology as is possible under their circumstances. At a minimum such service should be available for the examination of all tissues removed at operation necropsy. A more complete service includes regular visits by the pathologist to the hospital, examination of all tissues removed, performance of necropsies and attendance at staff meetings. Staff members must plan to use such service as is available to its fullest extent. At one hospital only the minimum service can be provided. Here one of the local staff members is designated as laboratory supervisor with the responsibility for making the laboratory work more serviceable to the staff, for performing all necropsies and for interpreting all pathologic reports. This supervisor sends a full report of his gross examination of all tissues to the pathologist so that all factors may be considered in the pathologist's report of the microscopic examination. Another hospital has been able to arrange for the pathologist to attend staff meetings. There from ten to fifteen minutes of each staff meeting is given over to a clinical pathologic conference using the tissues removed during the month and any available necropsy material as the basis of discussion. The staffs of these hospitals have taken as their ideal the willingness of members to review their clinical judgment objectively with the assistance of the pathologist's report and to face their clinical results at the necropsy table. The hospitals are teaching hospitals.

Finally the teaching values of a hospital depend on the willingness of the staff members as a group to pool their individual experiences without reservation into a common fund of knowledge to set up standards as a guide for their day to day hospital practice, to record their experience in an indexed library of clinical records, to consult freely with one another regarding individual patients, to lose no opportunity to check accurately their diagnoses and treatments, to study their recorded experiences in a constant attempt to improve their methods.

DEPRECIATION IN HOSPITAL BUILDINGS

VICTOR R. LUNDY, N.A.I. and LOTTIE L. CRAWFORD, M.A.I.
SAN DIEGO, CALIF.

At the request of Mercy Hospital, San Diego, a survey was recently made of 1,000 hospitals accredited by the American Medical Association to ascertain the economic life of such an institutional building. Questionnaires were sent to all hospitals which were non-profit and proprietary institutions in California with fifty beds or more and in other states with 100 beds or over. Only those hospitals which might be considered as operating on a competitive basis were included. Information was returned on 384 of these properties.

Results of this survey when tabulated showed that in the 20 years and under age group not only had a number of hospitals been demolished but 20 per cent of them had required new capital expenditures for modernization. In the 20 to 30 year age group 72 per cent were reported as either modernized or demolished. Consid-

ering all reporting hospitals it was indicated that, before reaching the age of 40 years, 60 per cent of them had been demolished or had undergone one or more extensive modernization programs.

This survey was limited, of course, and results are not conclusive; but they do appear to support the conclusion that the probability of any hospital enjoying, without the addition of large amounts of new capital, an economic life of much more than thirty-five years is extremely remote and that a depreciation factor of at least 3 per cent as advocated by some hospital authorities is none too great.

Complete tabulation of results of this survey are presented herewith.

Opportunities for the appraisal of hospital properties are comparatively rare and there is little to be found

in appraisal literature dealing with this subject, the extent of the discourse on hospitals being that they are service properties and as such are to be appraised on a cost less depreciation basis.

Hospitals in our opinion, however, have in numerous cases many of the attributes of investment properties. The plant and equipment, the personnel, the receipts and disbursements, and the problems of management in a hospital are often more intricate than in those of large and important commercial enterprises, and the necessity for most of them to earn a return commensurate with the capital investment which they represent is no less than it is in the case of hotels, apartments and similar enterprises, which have, as do hospitals, space and service for sale and the investment nature of which is recognized. To complicate the situation further, there is the matter of necessary free service or charity cases.

Economic obsolescence in appraisal practice is that phase of depreciation which has to do with loss of value due to adverse economic factors not inherent in the property but rather environing it. In hospitals there is a phase of economic obsolescence which occurs in few other types of property. A hospital is subject to peculiar economic hazards. It is a civic and social institution which, unless it cooperates freely in promoting community well being, is thought of as not performing the task for which it was intended and which public opinion insists that it shall perform. The result of this situation is that it is exceedingly difficult to operate a hospital on a strictly commercial basis and, to the extent that its efforts are devoted to charitable activity and free service, it becomes uneconomic and suffers loss of value accordingly, as it grows impossible for it to earn a legitimate return on the capital investment which it represents.

In all states, with the exception of California, New Mexico and Wyoming, this situation is recognized and an effort to compensate for it is made by the elimination of taxes wholly or in part. Where no such tax concession is made, there appears to be logic to the contention that, so far as charitable activity results in a loss of capital value, the inequality which thus arises should be adjusted by a proportionate reduction in valuation in tax purposes.

In any consideration of a hospital as an investment property, cognizance must be taken of the cost of the charitable or free contribution. If the institution were

free to delegate this portion of its function to the state where it really belongs, it could devote this portion of its plant to income producing activities. As an illustration, let us say that one third of the plant of the entire hospital is devoted to charitable works. We must then consider that the property has suffered from economic obsolescence the loss of one third of its value.

Necessarily in any financial statement made for the purpose of obtaining financing, whether through a bond issue or a direct loan from a financial institution, this loss of value must be considered. If some public recognition could be obtained of this social demand to the

Number in group.....	126	92	75	48	40	381
Percentage of total.....	32	25	20	13	10	100

These figures are the result of a questionnaire sent to 1,003 hospitals throughout the United States accredited by the American Medical Association and excluding all city, county, state and federal hospitals or those of fraternal or industrial organizations. Only those were considered for which the making of a profit might be an important consideration. Included were such hospitals in California of fifty or more beds and in other states of 100 or more. Information was returned on a total of 381 hospitals.

extent that state or municipal aid was given, the financing of hospitals could be made much more simple.

With the tendency toward a more general use of hospitals in minor ailments we can, in our opinion, expect an acceleration of obsolescence. Expenditures for modernization and upkeep will necessarily increase in order to arrest this tendency. Without a doubt many hospitals which have coasted along on their reputations will find it necessary to make major expenditures in order to maintain their incomes and compete with more modern institutions.

923 Seventh Avenue.

GRADUATE MEDICAL EDUCATION

PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

VERMONT

At the 1938 annual meeting of the Vermont State Medical Society the secretary, Dr. B. F. Cook, suggested more active cooperation between the Vermont Department of Public Health, the Medical College of the University of Vermont and the state medical society. In the secretary's report for 1939 it was stated that such cooperation had been secured and had resulted in benefit to the public and to the profession.

For the past five years the state medical society has held two day spring clinical meetings in Burlington with the active participation of the medical college. Lectures, demonstrations and clinics are given in the hospital and other buildings of the college. General and special aspects of medicine and surgery are considered, the sessions beginning at 9:30 each morning with small group demonstrations and continuing through the evening. Attendance has averaged about 225.

Each fall there is a two day regular meeting of the state society. During the past two years this has been held in Burlington. In addition to lectures the 1939 meeting included a symposium on obstetrics in which six Vermont and out of state physicians participated; the annual attendance has averaged 200. Of the 501 licensed physicians in the state, 392 are members of the Vermont State Medical Society.

The Commonwealth Fund of New York has provided physicians practicing in the rural sections of Vermont with fellowships which permit graduate study in medical centers outside the state. Fourteen men practicing in thirteen different areas spent from one to three months in continuation study during the past year. All but four of these physicians had availed themselves of this opportunity on previous occasions. The conditions of fellowship followed the same general pattern as in Maine and New Hampshire. The secretary of the state medical society accepts applications for the Commonwealth Fund.

In 1938 the state medical society aided in the establishment of a library in connection with the medical library of the university at Burlington. Ample quarters and supervision have been provided for periodicals and books donated or purchased by members of the society. An annual allotment of \$150 has been made to develop this library.

During the same year the state society cooperated with the state department of public health in launching a statewide program for the control of pneumonia. For this purpose the state society lent \$1,000 to the department of public health to aid in the maintenance of a fund for the purchase of serum. This loan has been repaid and the program has been generally considered successful.

Beginning in 1936 the Division of Maternal and Child Welfare of the Vermont Department of Public Health held itinerant lectures and demonstrations in six county medical societies. Three hour programs in each subject were available at monthly intervals for three times. Movies were utilized whenever possible.

During 1936-1937 three programs were given in each county society. In 1937-1938 the subjects were varied and, from the list of twenty-four topics submitted, many related to general medicine and surgery; county societies could make their own selections. Teams of two or more speakers were furnished for these discussions. The same plan was followed in 1938-1939. In addition there was a symposium on medicine and dentistry in which two physicians and two dentists participated. This full day program was given in four sections of the state. Other symposiums, on ovarian pathology, on infections of the upper respiratory tract and on obstetric and general anesthesia, have been given with both Vermont and out of state physicians participating.

During 1938-1939 a total of ten obstetric lectures and twelve pediatric lectures were held in ten places with an attendance of approximately 200 physicians. This was an increase over 1937-1938. The obstetric lectures were given in eight communities and pediatric in seven, with a total attendance of 128.

OFFICIAL NOTES

THE NEW YORK SESSION

Meeting Places

Meeting places for the House of Delegates, the General Scientific Meetings, the Sections of the Scientific Assembly and the Scientific and Technical Exhibits at the annual session of the American Medical Association to be held in New York June 10 to 14, 1940, will be as follows:

HOUSE OF DELEGATES: The Waldorf-Astoria, Basildon and Jade rooms.

GENERAL SCIENTIFIC MEETINGS: The Waldorf-Astoria, Ballroom, and the Commodore, Grand Ballroom.

REGISTRATION AND SCIENTIFIC AND TECHNICAL EXHIBITS: Grand Central Palace.

SYMPOSIUM ON HEALTH EDUCATION: Hotel Roosevelt, Grand Ballroom.

SECTIONS OF THE SCIENTIFIC ASSEMBLY

PRACTICE OF MEDICINE: The Waldorf-Astoria, Ballroom.

SURGERY, GENERAL AND ABDOMINAL: The Commodore, Grand Ballroom.

OBSTETRICS AND GYNECOLOGY: The Commodore, Grand Ballroom.

OPHTHALMOLOGY: Hotel Roosevelt, Grand Ballroom.

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY: Hotel Roosevelt, Grand Ballroom.

PEDIATRICS: The Waldorf-Astoria, Ballroom.

PHARMACOLOGY AND THERAPEUTICS: The Biltmore, Music Room.

PATHOLOGY AND PHYSIOLOGY: The Biltmore, Music Room.

NERVOUS AND MENTAL DISEASES: The Biltmore, Ballroom.

DERMATOLOGY AND SYPHILOLOGY: The Commodore, West Ballroom.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH: Hotel Roosevelt, Hendrik Hudson Room.

UROLOGY: The Commodore, West Ballroom.

ORTHOPEDIC SURGERY: The Biltmore, Ballroom.

GASTRO-ENTEROLOGY AND PROCTOLOGY: Hotel Roosevelt, Hendrik Hudson Room.

RADIOLOGY: The Commodore, East Ballroom.

MISCELLANEOUS TOPICS, SESSION ON ANESTHESIA: The Commodore, East Ballroom.

ADDITIONAL SPEAKERS AT ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

Supplementing the preliminary program printed in THE JOURNAL December 9, the following speakers will participate in the Annual Congress on Medical Education and Licensure to be held in Chicago Feb. 12 and 13, 1940:

Presidential Address.

Roy B. Harrison, M.D., President, Federation of State Medical Boards of the United States, New Orleans.

Opportunities for a Medical Career in the Federal Civil Service.
A. Ray Dawson, M.D., Senior Medical Officer, Examining Division, United States Civil Service Commission, Washington, D. C.

(Subject to Be Announced.)

Ross T. McIntire, M.D., Rear Admiral, Medical Corps, and Surgeon General, United States Navy, Washington, D. C.

Inter-American Relations in Medical Education and Licensure.
Walter L. Biering, M.D., Secretary-Treasurer, Federation of State Medical Boards of the United States, Des Moines, Iowa.

Relationship Between Advertising and the Practice of Medicine.
K. E. Miller, M.D., Senior Surgeon, United States Public Health Service, Federal Trade Commission, Washington, D. C.

Advisory Council on Medical Education as Related to Licensure.
Willard C. Rappleye, M.D., Dean, Columbia University College of Physicians and Surgeons, New York.

The Philosophic Trend of Medical Practice Laws.

H. M. Platter, M.D., Secretary, Ohio State Medical Board, Columbus.

The Advantages of a Single State Board of Medical Examiners.

J. N. Baker, Secretary, Alabama State Board of Medical Examiners, Montgomery.

CORRECTION

Program for Instruction of Interns.—In the program for the Annual Congress on Medical Education and Hospitals (THE JOURNAL, December 9, p. 2157) one of the speakers on the subject "Program for Instruction of Interns" was printed as Nathan Davis, M.D., New York. This name should have been Nathan Smith, M.D., New York.

WOMAN'S AUXILIARY

New Jersey

The board of directors of the auxiliary to the Medical Society of New Jersey met in Camden October 29. Speakers were Mrs. Rollo K. Packard, president of the auxiliary to the American Medical Association, and Dr. LeRoy A. Wilkes, executive officer, *Journal of the Medical Society of New Jersey*.

The auxiliary to the Atlantic County Medical Society met in Atlantic City October 13. Speakers were Mrs. McDonnell, president, and Mrs. J. H. Hornberger, corresponding secretary

of the auxiliary to the Medical Society of New Jersey, and Mr. Frank G. Farley, assemblyman from Atlantic County in the New Jersey legislature. Mr. Farley spoke on constructive legislation.

South Dakota

The board of directors of the auxiliary to the South Dakota State Medical Association met in Huron October 3. The president, Mrs. A. E. Johnson, suggested that members study the works of prominent members of the medical profession. The special work of the auxiliary is its benevolent fund.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Annual Art Exhibit.—The Los Angeles Physicians' Art Society will hold its second annual exhibit in the lounge of the Los Angeles County Medical Association January 8-31. All members of the county medical association are invited to submit art work for this exhibit. There will be five classes of art for exhibition: modeling and sculpture (including wood-carving), painting, drawing, photography and handicraft. Additional information may be obtained from either Dr. Katherine Close, secretary, or Dr. Harold L. Thompson, president.

Annual Surgical Meeting.—The Los Angeles Surgical Society held its annual meeting December 13. The following program was presented:

Dr. James A. Jackson, Madison, Wis., Open Reduction Treatment of Fractures.
Dr. Albert H. Montgomery, Chicago, Abdominal Tumors in Childhood.
Dr. Earl C. Padgett, Kansas City, Mo., Superficial and Deep Intermediate Skin Grafts as Cut with the Dermotome.
Dr. Kellogg Speed, Chicago, Pitfalls in Bone Tumor Diagnosis and Prognosis.
Dr. Rollin Russell Best, Omaha, The Biliary Flush as an Aid in the Management of Biliary Tract Disease.
Dr. Willis D. Gatch, Indianapolis, Surgical Treatment of Acute Lesions of the Upper Abdomen.
Dr. Raymond W. McNealy, Chicago, Perforation in Peptic Ulcer: A Critical Review of 700 Cases.
Dr. Charles W. Mayo, Rochester, Minn., Combined Abdominoperineal Resection for Malignancy of the Lower Bowel.

COLORADO

New Officers of Hospital Association.—Mr. Frank J. Walter, Denver, was chosen president-elect of the Colorado Hospital Association at its annual meeting November 15 and Mr. R. J. Brown, Denver, was installed as president. Dr. Bertram B. Jaffa, Denver, is executive secretary. It was decided to hold the 1940 meeting in Denver November 13. Among the speakers was Dr. Bert W. Caldwell, Chicago, executive secretary, American Hospital Association, who discussed "Nongovernment Hospitals and the Federal Health Program."

Society News.—At a meeting of the Arapahoe County Medical Society November 27 Drs. Osgoode S. Philpott and Isadore Gersch of Denver discussed syphilis and gonorrhea respectively. The Fremont County Medical Society was addressed in Florence November 27 by Drs. Kon Wyatt, Canon City, on "Functional Disorders of the Colon" and Elwood B. Lynch, Canon City, "Practical Points on Diagnosis and Treatment of Diseases of the Liver."—Dr. Roland M. Klemme, St. Louis, addressed the Colorado Neurological Society in Denver December 16 on "Surgical Treatment of Paralysis Agitans, Athetosis and Dystonia."

CONNECTICUT

Hartford Times Radio Blood Donors League.—The Hartford Times Radio Blood Donors League has recently been established through the cooperation of the newspaper and its radio division WTHT. The league aims to secure a group of volunteers who are willing to give their blood for a transfusion without any monetary compensation. It is designed for use only in the four public hospitals in Hartford and is an emergency service intended solely for patients who are positively unable to secure a necessary transfusion in any other way. It is not available to persons able to pay or who have friends or relatives who can supply the transfusions. No call requesting a donor of a transfusion will be accepted except from a hospital or attending physician. Twenty-four hour service is provided. The four hospitals and the Hartford County Medical Association are cooperating in typing the volunteers. Of the 150 volunteers recorded November 21 sixty had been typed and donors for fifteen transfusions had already been supplied. Members of the committee in charge of the league are Ward Duffy, managing editor of the Hartford Times; Bob Martineau, program director of WTHT; Police Chief Butler of the Hartford police department, and Drs. Louis P. Hastings, Perry T. Hough, Abraham M. Schaefer and Ralph E. Kendall, chief pathologists at the St. Francis, Municipal, Mount

Sinai and Hartford hospitals, respectively, and Dr. Harry L. F. Locke, chairman of the medical information bureau of the Hartford Medical Society and the Hartford County Medical Association.

ILLINOIS

Society News.—Dr. Edward L. Compere, Chicago, was reelected president of the Illinois Association for the Crippled at its recent meeting in Chicago.—The Champaign County Medical Society was addressed November 9 by Dr. Roland M. Klemme, St. Louis, on "Surgical Treatment of Parkinson's Disease."—Dr. Joseph L. Baer, Chicago, addressed the Lake County Medical Society December 5 on "Prevention of Maternal Mortality."—Dr. Otto H. Schwarz, St. Louis, discussed "Use of X-Ray in Obstetrics" before the Sangamon County Medical Society, Springfield, December 7.

State Health Conference.—The annual state conference on public health was held in Springfield December 7-8. Among the speakers were:

Clair Turner, Dr. P.H., Cambridge, Mass., Educating the Public for Health.
Dr. Esmond R. Long, Philadelphia, The Tuberculin Test.
Dr. Theodore R. Meyer, Clayton, Mo., A Practical Program in Sanitation.
Dr. Harry S. Gradle, Chicago, Sight Conservation.
Dr. Franklin G. Ebaugh, Denver, Mental Hygiene in Public Health.
Dr. Warren F. Draper, Washington, D. C., The Federal Health Program.
Dr. Fred Moore, Des Moines, Iowa, School Health Programs.
Dr. Everett D. Plass, Iowa City, A Rural and Small Town Maternity Hygiene Program.
Reuben L. Kahn, Se.D., Ann Arbor, Mich., Serology in Syphilis.

A symposium on laws requiring diagnostic tests featured the luncheon for health officers with the following speakers: Dr. Kahn, Howard J. Shaughnessy, Ph.D., chief of the division of laboratories, state department of health, and Dr. Edward A. Piszczek, of the Chicago department of health.

Chicago

Dr. Pusey to Lecture on History of Chicago Medicine.—Dr. William Allen Pusey will deliver a public lecture in the auditorium of the Museum of Science and Industry, west pavilion, Jackson Park, January 9, on "High Lights in the History of Chicago Medicine." The lecture is sponsored by the Institute of Medicine of Chicago in conjunction with the Chicago Historical Society and the Society of Medical History of Chicago.

Branch Meetings.—At a meeting of the Evanston Branch of the Chicago Medical Society November 3 Dr. James Murray Kinsman, Louisville, Ky., discussed "Present Status of Sulfapyridine." Dr. James C. White, Boston, addressed the North Side Branch November 2 on "Neurological Treatment of Visceral Pain." At a meeting of the Englewood Branch November 7 Dr. Arthur Steindler, Iowa City, discussed "Fracture Malunion of the Ankle Joint." Dr. Anton J. Carlson discussed "Black Oxen and Toggenburg Goats" before a meeting of the Aux Plaines Branch December 15. A symposium on pneumonia was presented before the Calumet Branch December 15 by Drs. Paul S. Rhoads, Evanston, Ill., and Ford K. Hick. Drs. Harry M. Hedge and Samuel J. Zakon, among others, addressed the Douglas Park Branch December 19 on "Diagnosis and Treatment of Naevi" and "The Management of Some Common Skin Diseases."

IOWA

University News.—Dr. Hale F. Shirley, assistant professor of psychiatry, State University of Iowa College of Medicine, Iowa City, has resigned to become assistant professor of psychiatry and pediatrics at Stanford University School of Medicine and director of the Child Guidance Clinic, San Francisco. Dr. Shirley graduated at Iowa in 1927.

Society News.—Dr. William Wayne Babcock, Philadelphia, discussed peritonitis before the Black Hawk County Medical Society in Waterloo October 23.—At a meeting of the Boone and Story county medical societies in Ames October 24 Dr. Horton C. Hinshaw, Rochester, Minn., spoke on "Pneumonia and Upper Respiratory Infections."—The Crawford County Medical Society was host to the dentists of the county and the wives of both groups at a dinner meeting recently; Dr. Harry N. Boyne, Omaha, spoke on "The Care of Facial Injuries."—Dr. Lester R. Dragstedt, Chicago, discussed "Etiology and Surgical Treatment of Gastroduodenal Ulcers" before the Dallas and Guthrie county medical societies at a meeting in Guthrie Center, October 25.—The quarterly conference of the Lee County Medical Society was addressed in Keokuk October 20 by the following, all of

Chicago: Drs. John I. Brewer, on "Uterine Bleeding"; Grant H. Laing, "Clinical Importance of Pylorospasm"; George W. Hall, "Newer Treatment of Mental and Nervous Diseases," and Fremont A. Chandler, "Low Back Pain."—At the sixty-fourth annual meeting of the Southeastern Iowa District Medical Society in Washington October 26 the speakers included Dr. George D. Jenkins, Burlington, on "The Newer Concepts in the Treatment of Gonorrhea."

MASSACHUSETTS

Dr. Castle Awarded Walter Reed Medal.—Dr. William B. Castle, professor of medicine, Harvard Medical School, Boston, was awarded the Walter Reed Medal November 21 at a meeting of the American Society of Tropical Medicine in Memphis, Tenn. The award was made for his "meritorious achievements in the field of tropical medicine, his outstanding leadership and scientific investigations which have resulted in most important additions to our knowledge of sprue and related anemias," newspapers reported. Dr. Richard P. Strong, Boston, presented the medal. It was the first award in four years. It is given only in years when there has been particularly outstanding work. Dr. Castle, a graduate of Harvard, has been a member of its teaching staff since 1923 and professor since 1937.

Committee to Develop Research in Pharmacotherapy.—A committee on pharmacotherapy has been established at Harvard University to develop research and improve graduate training in the field of pharmacology and experimental therapeutics, coordinating the efforts of practicing physicians and Harvard scientists in biology, chemistry and medicine. Funds to support the work of the committee for the next five years have been donated by a group of corporations interested in medical and therapeutic research. Dr. Soma Weiss, Hersey professor of the theory and practice of physic at Harvard, is chairman of the committee. Other members are Dr. Fuller Albright, assistant professor of medicine; Dr. Henry K. Beecher, associate in anesthesia; Dr. Sidney Burwell, dean of the medical school, ex officio; Dr. Walter B. Cannon, George Higginson professor of physiology; Dr. William B. Castle, professor of medicine; James B. Conant, LL.D., president of the university, ex officio; Louis F. Fieser, Ph.D., professor of chemistry; A. Baird Hastings, Ph.D., Hamilton Kuhn professor of biological chemistry; Frederick L. Hisaw, Ph.D., professor of zoology; Dr. Otto Kraye, associate professor of comparative pharmacology, and Reginald P. Linstead, professor of chemistry. It is hoped that through the work of the committee pharmacology and experimental therapeutics will be more effectively cultivated and that an opportunity will be afforded for a new and improved graduate training in the field of pharmacology and experimental therapeutics.

MICHIGAN

Personal.—Dr. James W. Hubly, recently first assistant in the department of surgery at the Mayo Clinic, Rochester, Minn., has been appointed head of the department of surgery at the Battle Creek Sanitarium, Battle Creek. Dr. Martin A. Mortensen, who for several years was a member of the staff in internal medicine, has returned to the sanitarium, it was announced recently by the newly appointed administrator, Dr. John E. Gorrell.

State Society Night.—The Wayne County Medical Society, Detroit, designated its meeting December 4 as "state society night." Included among the speakers following a dinner in their honor were:

Dr. Burton R. Corbus, Grand Rapids, president of the state society, The Function of the State Medical Society.
Dr. Henry A. Luce, Detroit, delegate to the American Medical Association, National Medical Activities.
Drs. Henry R. Carstens and Andrew S. Brunk, both of Detroit, chairman and vice chairman of the council, respectively, and Dr. L. Fernald Foster, Bay City, secretary, Michigan Medical Service.
William J. Burns, executive secretary, Medical Welfare.

Society News.—Dr. Carl E. Badgley, Ann Arbor, discussed "Bone Surgery" before the Muskegon County Medical Society in Muskegon November 17.—Dr. Traian Leucutia, Detroit, discussed "X-Ray Therapy of Cancer" before the Oakland County Medical Society November 1 in Birmingham.—At the second meeting of the Michigan Society of Neurology and Psychiatry November 30 in Dearborn the speakers were Drs. Hawley S. Sanford, Detroit, on "Epileptic Phenomena Associated with Tumors of the Temporal Lobe," and Russell T. Costello, Detroit, "Migraine and Trigeminal Neuralgia Occurring in a Neuropathic Family."

MISSOURI

Dr. Baumgarten Named Editor of State Journal.—Dr. Walter Baumgarten, St. Louis, has been elected editor of *The Journal of the Missouri State Medical Association* to succeed Dr. Edward J. Goodwin, who retired last year and was elected secretary-editor emeritus. Dr. Baumgarten graduated at Washington University School of Medicine, St. Louis, in 1896.

Dr. Doisy Receives Annual Award.—Edward A. Doisy, Ph.D., professor and director of the department of biological chemistry, St. Louis University School of Medicine, St. Louis, recently received the seventh annual St. Louis Award at a public ceremony in the mayor's office, according to *Science*. The award, \$1,000 and a certificate, is the gift of an anonymous donor. Graduating at the University of Illinois in 1914, Dr. Doisy took his doctor's degree in 1920 at Harvard University. He served on the staffs of the medical schools of Harvard and Washington University before joining St. Louis University in 1923.

NEW YORK

District Meeting.—Two symposiums made up the program of the annual meeting of the Second District Branch of the Medical Society of the State of New York in Garden City November 16. Dr. Henry M. Moses, Brooklyn, presided at a morning session on neoplasms of the chest with the following speakers: Drs. Matthew G. Golden, Brooklyn; Irving S. Startz, Elmhurst; Carl H. Greene, New York; Raphael A. Bendove, New York; Alfred Angrist, Jamaica, and William H. Field, Brooklyn. Tuberculosis was the afternoon topic, with Dr. Charles E. Hamilton, Brooklyn, as chairman and the following speakers: Drs. Foster Murray, Abraham H. Levy, Edwin J. Grace, Peter Amazon, Brooklyn, James C. Walsh, Farmingdale, and Carl A. Hettesheimer, Hempstead.

New York City

Doctors' Orchestra Opens Concert Season.—The Doctors' Orchestral Society of New York gave its first concert of the season December 8 at the New York Philanthropic League Hall. The program included the Bach Brandenburg Concerto in G major No. 3; a Mozart quintet in A major; the andante cantabile from Tchaikowsky's String Quartet No. 11; compositions for violin and piano by Eda Rapoport, wife of a physician, and a group of solos by Miss Marcella Uhl. Ignatz Waghalter is conductor of the orchestra.

Memorial Meeting for Dr. Park.—Civic, educational and medical leaders held a memorial meeting November 28 in honor of the late Dr. William H. Park. Speakers included Mayor La Guardia; Harry Woodburn Chase, chancellor of New York University; Dr. Malcolm Goodridge, president of the New York Academy of Medicine; Dr. Anna W. Williams, former assistant director of the city health department's bacteriology laboratory under Dr. Park, and Dr. Augustus B. Wadsworth, director of laboratories and research, state department of health, Albany.

Dr. Bassler Honored.—The November-December issue of the *Review of Gastroenterology* was dedicated to Dr. Anthony Bassler in honor of his sixty-fifth birthday. Dr. Bassler, a native of New York, graduated in the last class from Bellevue Hospital Medical College before its merger with the New York University Medical College in 1898. He was successively lecturer in pediatrics, pathology and internal medicine at the new school from 1900 to 1910; clinical professor of physical diagnosis at New York Polyclinic Medical School and Hospital, 1911-1914, and professor of gastroenterology 1915 to 1925; professor of gastroenterology at Fordham University Medical College, 1915-1920. For the past four years Dr. Bassler has been president of the National Gastroenterological Association. He is consulting gastro-enterologist to several hospitals in New York and surrounding towns. He is the author of four books in his specialty and has contributed much to periodic literature.

Society News.—Speakers at a meeting of the New York chapter of the National Gastroenterological Association November 20 were Drs. William A. Steel, Philadelphia, on "Cholecystogastrotomy and Duodenostomy"; William A. Swalm and Lester Morrison, Philadelphia, "A New Liver Function Test."—Drs. Isidor C. Rubin and Bruce P. Webster addressed the New York Endocrinological Society November 22 on "Endocrine Therapy in Sterility: A Critical Review" and "Disturbances of Normal Mechanism of Puberty and Their Management" respectively.—Dr. Roderick V. Grace addressed the New York Surgical Society November 22 on "Surgery of

the Thyroid."—Drs. Henry Graham and Charles D. Sawyer addressed the New York Surgical Society November 8 on "Peritoneoscopy."—Drs. Max Pinner and Edgar Mayer addressed the Bronx County Medical Society November 15 on "Epidemiology and Pathogenesis of Pulmonary Tuberculosis" and "Diagnosis and Treatment of Pulmonary Tuberculosis" respectively.—Dr. Philip Sacks addressed the Bronx Otolaryngological Society November 28 on "Pneumococcal Meningitis, a Review of the Literature and Report of a Type XVIII Recovery of Otic Origin."—The Tuberculosis Sanatorium Conference of Metropolitan New York, which also includes Long Island, New Jersey and part of Connecticut, has formed a nursing and social service section.

NORTH CAROLINA

New Industrial Hygiene Director.—Dr. Thomas F. Vestal, Worcester, Mass., has been appointed medical director of the division of industrial hygiene in the state board of health. He succeeds Dr. Herman F. Easom, who recently resigned. Dr. Vestal is a native of North Carolina and a graduate of the University of Maryland School of Medicine.

District Meetings.—The Eighth District Medical Society held its annual meeting in High Point November 2, with Dr. William Halsey Barker, Baltimore, as the guest speaker on "Sulfanilamide, Sulfapyridine and Allied Compounds." A symposium on treatment of diabetes was presented by Drs. Opie Norris Smith, Greensboro; William H. Sprunt Jr., Winston-Salem; Roy C. Mitchell, Mount Airy, and Thomas D. Tyson Jr., High Point.—Speakers at a meeting of the Second District Medical Society in Washington October 31 were Drs. William M. Nicholson, Durham, on "Treatment of Diabetes with Modified and Unmodified Insulin"; August R. Peters Jr., Washington, "Sulfapyridine in the Treatment of Pneumonia," and Mr. H. S. Ward, attorney, "The Doctor in Court."—Dr. Eugene P. Pendergrass, Philadelphia, addressed the semi-annual meeting of the Tenth District Medical Society in Marion November 10 on cancer of the breast.

OHIO

Hospital Celebrates Golden Jubilee.—The Christ Hospital, Cincinnati, marked its golden jubilee with a dinner December 1 at which the principal feature was the presentation to the hospital of portraits of Drs. John C. Oliver and Edwin W. Mitchell. Dr. Oliver is the only living member of the original staff of the hospital and Dr. Mitchell has been a member since 1914.

Dr. Freiberg Honored.—The president of the University of Cincinnati and the faculty of the College of Medicine sponsored a dinner December 6 at the Netherland Plaza Hotel in honor of Dr. Albert H. Freiberg, recently retired professor of orthopedic surgery. Dr. Martin H. Fischer was toastmaster and the speakers were Raymond Walters, LL.D., president of the university; Drs. Stanley E. Dorst, Mont R. Reid and David I. Wolfstein, and the Rev. Jesse Halsey, pastor of the Seventh Presbyterian Church. A portrait of Dr. Freiberg was presented to him.

Society News.—Dr. Winchell M. Craig, Rochester, Minn., addressed the Warren County Medical Society, Franklin, November 22 on "Surgical Treatment of Hypertension."—Dr. Arthur Carlton Ernstene, Cleveland, addressed the Ashtabula County Medical Society, Conneaut, recently on "Common Errors in Cardiac Diagnosis."—Dr. Deane H. Northrup, Marietta, addressed the Washington County Medical Association, Marietta, on "Burns and Their Treatment"; Drs. George F. Swan, Cambridge, "Medical Organization in Relation to Public Needs," and William L. Denny, Cambridge, new state laws on relief.—Dr. Martin H. Fischer, Cincinnati, addressed the Butler County Medical Society, Hamilton, November 29 on arteriosclerosis.—Dr. Emil Novak, Baltimore, addressed the Academy of Medicine of Cincinnati December 19 on "The Endocrine Influence of Certain Ovarian Tumors." Dr. Maxwell Finland, Boston, spoke December 5 on "Serotherapy and Chemotherapy of Pneumonia."

OREGON

Personal.—Dr. Edward J. Dehne, formerly of Astoria, has been appointed health officer of Coos County to succeed Dr. Leslie S. Porter, Eugene, who resigned to join the University of Oregon health service.

Society News.—Drs. Robin M. Overstreet and Willis B. Shepard, Eugene, addressed the Lane County Medical Society, Eugene, October 23, on "Abdominal Symptoms in Childhood"

and "Motor Anomalies of the Eye" respectively.—Dr. Roger Anderson, Seattle, addressed the Polk-Yamhill-Marion Counties Medical Society, Salem, recently on "Fractures of the Clavicle and Injuries in the Region of the Shoulder Joint" and "Leg Fractures." Dr. Donald R. Laird, Portland, addressed the society November 7 on "Proctologic Problems of General Interest."

PENNSYLVANIA

Society News.—Drs. William J. Logue, Creed C. Glass, Meyersdale, and Alexander Solosko, Salisbury, presented a symposium on "Subacute Bacterial Endocarditis" before the Bedford County Medical Society, Bedford, November 28.—Dr. Harry D. Lees, Philadelphia, addressed the Delaware County Medical Society, Chester, December 14 on "Pennsylvania's Tuberculosis Problem."—Dr. Abraham Cantarow, Philadelphia, addressed the Harrisburg Academy of Medicine December 19 on "Effective Use of the Clinical Laboratory."—Dr. Joseph B. DeLee, Chicago, addressed the Lycoming County Medical Society, Williamsport, December 8 on eclampsia.

Philadelphia

Dr. Morgan Honored.—Alumni of the former Medico-Chirurgical College of Philadelphia made of their annual reunion dinner in November a celebration of the seventieth birthday of Dr. Arthur C. Morgan, long active in the affairs of the alumni association. Dr. Morgan received a testimonial volume signed by every living alumnus of the school, from which he graduated in 1897. The year following his graduation he became a member of the faculty and served until the school was taken over in 1916 by the University of Pennsylvania to be developed as a graduate school. In the new school he was associate professor of medicine from 1916 to 1922 and for several years was associate in medicine in the undergraduate department of the university. In 1922 he went to Temple University School of Medicine as professor of applied therapeutics, remaining in that chair till 1928. He has been emeritus professor of clinical medicine since 1930. Dr. Morgan has been active in medical organizations, as president of the Philadelphia County Medical Society, as president of the Medical Society of the State of Pennsylvania, and as member of the House of Delegates of the American Medical Association. His hospital affiliations have included the Frankford Hospital, of which he was physician in chief and medical director for eight years, and the Medico-Chirurgical, Polyclinic, Samaritan and Garretson hospitals, where he has been at various times visiting physician. He was also a member of the Pennsylvania State Board of Medical Examiners for several years.

VIRGINIA

Regional Meeting.—The Southside Virginia Medical Association held its quarterly session in Petersburg December 12 with the following speakers, all of Richmond, on the program:

- Drs. James W. Whitfield Jr. and Herman W. Farber, Care of the Skin in a Newborn Child.
- Dr. Harry Hudnall Ware Jr., Management of Placenta Praevia.
- Dr. Douglas G. Chapman, The Heart Beat Mechanism in Health and Disease.
- Dr. Oscar L. Hite, Complications Resulting from the Use of Sulfapyridine.
- Dr. Thomas F. Wheeldon, Use of the Smith-Petersen Nail in Fractures of the Neck of the Femur.

This society is made up of fifteen counties and the cities of Norfolk, Suffolk, Petersburg and Hopewell.

WEST VIRGINIA

Cancer Institute in Martinsburg.—The Eastern Panhandle Medical Society sponsored a cancer institute for the Eastern West Virginia division of the Women's Field Army of the American Society for the Control of Cancer December 13 in Martinsburg. Drs. Leopold Clarence Cohn, Baltimore, conducted a clinic and Dr. William Neill Jr., Baltimore, made an address on "Facts of Interest to Women Concerning Cancer." The visiting physicians also addressed the society at its regular luncheon meeting.

Society News.—Dr. Frank H. Lahey, Boston, addressed the Ohio County Medical Society, Wheeling, December 1, on "Various Thyroid States, Their Diagnosis and Management."—Dr. Mont R. Reid, Cincinnati, addressed the Kanawha Medical Society, Charleston, November 14 on "Healing of Wounds."—Dr. Hugh W. MacMillan, Cincinnati, also a dentist, addressed the Logan County Medical Society, Logan, November 8 on "Medical and Dental Conditions of the Head"

and Neck."—Drs. Albert H. Hoge and Marshall W. Sinclair, Bluefield, addressed the Mercer County Medical Society, Princeton, November 16 on "Fads and Fallacies of Endocrinotherapy" and "Breast Tumors" respectively.

WISCONSIN

State Society Moves.—The State Medical Society of Wisconsin has moved its offices to 917 Tenney Building, Madison. Future correspondence should be sent to that address.

Lippitt Memorial Lecture.—The fifth annual Lippitt Memorial Lecture at Marquette University School of Medicine will be delivered January 19 by Dr. Harry Goldblatt, professor of experimental pathology and associate director of the Institute of Pathology, Western Reserve University School of Medicine, Cleveland. Dr. Goldblatt's subject will be "Experimental Observations on the Pathogenesis and Treatment of Hypertension."

Society News.—The Central Wisconsin Society of Ophthalmology and Otolaryngology held its fall meeting in Wausau October 28-29. Dr. Henry L. Williams, Rochester, Minn., presented papers on "Results of Endonasal Window Operation for Maxillary Sinusitis" and "Surgery of Chronic Pansinusitis," and Dr. Charles W. Rucker, Rochester, on "Perimetry and the Visual Pathway" and "Treatment of Toxic Amblyopia." Dr. Archibald H. Beard, Minneapolis, addressed the Barron-Washburn-Sawyer-Burnett Counties Medical Society, Green Bay, November 7, on "Some Recent Theories on Diabetes, Including Therapy" and a motion picture on "Intracranial Injuries of the Newborn" by Dr. Pascal Brooke Bland, Philadelphia. Dr. Albert G. Schutte, Milwaukee, addressed the Brown-Kewaunee-Door Counties Medical Society, Green Bay, November 9, on "Diagnosis and Treatment of Common Rectal Conditions." Drs. John T. F. Gallagher and Luther E. Holmgren, Madison, addressed the Chippewa County Medical Society, Chippewa Falls, November 7 on "Open Reduction of Fractures" and "Spinal Anesthesia in Surgery" respectively. Dr. Walter C. Alvarez, Rochester, Minn., was the guest speaker before the Dane County Medical Society, Madison, November 14 on "What to Do for the Woman Who Is Always Complaining."

GENERAL

Special Society Election.—Dr. Spencer Braden, Cleveland, was elected president of the Academy of Neurosurgery at the annual meeting in New Orleans in October. Dr. Francis Murphey, Memphis, Tenn., was reelected secretary. The 1940 meeting will be in Cleveland.

Pediatric Awards.—The American Academy of Pediatrics at its annual meeting in Cincinnati November 17 presented the E. Mead Johnson awards of \$500 each to Drs. Frederic A. Gibbs, Boston, and Dorothy H. Andersen, New York. Dr. Gibbs was honored for his contribution to the knowledge of epilepsy and Dr. Andersen for her research on pancreatic disorders.

Southern Medical Election.—Dr. Quitman U. Newell, St. Louis, was chosen president-elect of the Southern Medical Association at the annual meeting in Memphis, Tenn., November 21-25 and Dr. Arthur T. McCormack, Louisville, Ky., was installed as president. Drs. Wilson L. Williamson, Memphis, and Ernst W. Bertner, Houston, Texas, were elected vice presidents. Next year's meeting will be in Louisville in November.

Northwest Regional Conference Changes Name.—The Northwest Regional Conference will henceforth be known as the National Conference on Medical Service. The conference is not official nor political, is not connected with any other organization or committee and its deliberations result in no resolutions or motions. It is informal, has no dues, by-laws or formal organizational structure. The fourteenth annual session will be held at the Palmer House, Chicago, Sunday Feb. 11, 1940. All state medical societies are invited to send representatives. Dr. L. Fernald Foster, Bay City, Mich., is president of the national conference and Dr. Forrest L. Loveland, Topeka, Kan., secretary.

New Films on Syphilis.—The American Social Hygiene Association has produced a documentary sound film, "With These Weapons," to aid in the campaign against syphilis. It has been prepared for distribution to schools, colleges, state and local health departments, women's clubs, social hygiene societies, churches and other organizations. The film opens with scenes illustrating the work of Schaudinn, Wassermann, Ehrlich and present day scientists and progresses to the principles of diagnosis and treatment, depicting the disease in its relation to individual and public health. Another film, entitled "Three Counties Against Syphilis," was produced by the U. S. Public Health Service to show the work of the trailer clinics for control of syphilis in three counties in Georgia.

Inter-American Society of Microbiology.—At the close of the recent International Congress of Microbiology in New York an Inter-American Society of Microbiology was organized with Dr. A. Sordelli, Buenos Aires, as the first president and Dr. Francesc Duran-Reynals, New Haven, Conn., as executive secretary. Two major problems which the society hopes to solve by this cooperation are (1) to devise a means for better exchange of results of studies in Latin and North America and (2) to effect a more intimate affiliation between the workers of all countries in study of diseases common to all. The new society plans to approach the solution of these problems by establishing an official journal and by organizing a congress. It is proposed that the journal will make its pages available to contributors from both Latin America and North America, the necessary translation being done in the United States. The proposed congress will be in Rio de Janeiro three years hence. Dr. J. C. N. Penido, Rio de Janeiro, was chosen to organize a committee to prepare for it.

Patients with Cancer Treated with Neutron Rays.—Cancer patients are now being treated with neutron rays produced by the cyclotron at the University of California, it was announced at the annual meeting of the National Advisory Cancer Council December 4. It is hoped that the rays from the 225 ton medical cyclotron at the university may break down cancer cells and effect, at least temporarily, some definite remission, according to a statement from the U. S. Public Health Service. The new 60 inch cyclotron occupies its own laboratory on the Berkeley campus of the university. In a report, Ernest O. Lawrence, Ph.D., who developed the cyclotron, for which he was awarded the Nobel Prize this year, stated:

The new installation has been steadily improved, and at the present time it is gratifying to report that it is performing even better than we had reason to expect. The outfit runs with complete steadiness and reliability when producing 100 micro-amperes of 16 million volt deuterons (or one micro-ampere of 32 million volt alpha particles), and under these conditions the output of neutron rays, gamma rays and radioactive substances is prodigious. The latter are being sent to many parts of the world for experimental purposes. Should it prove desirable, we will be able to arrange treatment ports to treat two or more patients simultaneously. These remarks likewise apply to gamma rays, for we have plenty of gamma radiation of the energy range above a million volts also available for therapy. We have found that the yield of radioactive substances has gone up according to expectations. For example, the yield of radioactive iodine at 16 million volts is twenty times greater than at eight million volts, and we can now manufacture enough of this material to use it for therapeutic purposes, should this prove desirable.

"Crude" Deaths in Large Cities.—The New York City Department of Health has published its annual comparison of vital statistics in twenty-four large cities of the United States for 1938. The cities have a total population of nearly 27,000,000. The general death rate was 10.6 per thousand of population and the infant mortality rate was 42 per thousand live births. The birth rate was 15.3. It is pointed out that the rates for the individual cities are "crude" rates and should not be used as indexes of the relative healthfulness of the cities. Detroit had the lowest general rate, 7.8, and San Francisco the lowest infant mortality rate, 29.6. Other cities with general death rates under 10 were Milwaukee 8.4; Los Angeles 9.3; Rochester, N. Y., 9.6; Chicago 9.7 and New York 9.8. New Orleans with 15.4 had the highest rate in the group and Denver was next with 14. In 1938 seventeen cities had infant mortality rates under 50 and nine of these had rates under 40. In 1929 only two of this number had rates under 50. Among the five cities with populations over a million, the rates for infant mortality were: New York 38.3; Chicago 33.7; Philadelphia 42.2; Detroit 41.4 and Los Angeles 56.8. In these large cities the puerperal mortality was reported to be: New York 3.5 per thousand live births; Chicago 2.7; Philadelphia 3.2; Detroit 3.3 and Los Angeles 3.2. The compilation also listed the death rates from several important causes. New Orleans had the highest typhoid rate, 5.5 per hundred thousand of population; the next highest was Jersey City with 1.2. New Orleans also had the highest tuberculosis death rate, with Washington, D. C., next; these rates were 95.2 and 82.8 respectively. Minneapolis had the lowest tuberculosis rate, 13.6. Denver had the highest diptheria death rate, 4.5, while Boston and Newark, N. J., had the lowest, 0.2. The highest cancer rate was reported from Boston, 203.5, and the lowest from Toledo, Ohio, 70.7. Pneumonia was highest in New Orleans, 150.7, lowest in Detroit, 41.6. The highest automobile death rate was in Denver, 35.2, and the lowest in Milwaukee and Jersey City, 9.5.

Medical Students and the War

The recently passed law of conscription for military service affects medical students, as many of them belong to the age group called up. But exemption is granted in the case of occupations of national importance for war purposes. As the fighting services make a considerable demand on the medical profession, it is important that medical students should continue their studies and become qualified. The authorities have decided that a medical student who has passed the first professional examination and completed two terms of anatomy and physiology is a member of a "reserved occupation." He is expected to continue his studies and is not liable for military service or eligible for national service of other kinds. If the necessity for maintaining himself away from home, resulting from the transference of his medical school to another area, causes financial difficulty, no state assistance is available to him. He should consult the dean of his medical school. A student who has not passed the first professional examination and completed two terms of anatomy and physiology is at liberty to continue his medical studies unless and until he is called up for medical service, provided his medical school can continue to provide a vacancy for him in the changed conditions. In the event of his completing the stated period of anatomy and physiology before his age group is called up, he will cease to be liable for military service and will be treated as "reserved." No decision has yet been reached regarding the release from military service of medical students who have reached a stage of the curriculum at which they would ordinarily be regarded as "reserved" but who, because of their prewar commitments to the army, are now serving as combatant officers or in the ranks.

The "Oslo Breakfast" in England

A new method in the feeding of children was presented some seven years ago by an experiment in a school in Oslo. Instead of a hot meal of the usual type served at midday, the children were given a breakfast composed of foods selected primarily with the object of making good the deficiencies in the home diet. The deficiency of animal protein was made good by a piece of goat's milk cheese and a glass of milk, which also supplied minerals and vitamins. There was entire wheat bread to supply vitamin B and the mineral salts lacking in white bread. Protection against scurvy, a danger in northern countries where cheap fruit is available for only a short part of the year, was given by half an apple or orange, a lettuce or a raw carrot, depending on the prevailing prices. In addition there was a good sized pat of butter to add more vitamins A and D. When the child had eaten this meal it was allowed, if still hungry, to fill up with bread and margarine. The experiment was such a success that this meal was adopted in almost every school in Norway and is now being tried out in the other Scandinavian countries. Both the development and the health of children were found to be better than when the hot meal of meat and cooked vegetables was provided.

The "Oslo breakfast" has been introduced into England and found highly satisfactory, but it is given as a dinner instead of breakfast and is called "the health dinner." In his report to the London County Council, just published, the school medical officer, Sir Frederick Menzies, states that the children taking the Oslo meal showed a greater increase in height and weight than children receiving the traditional English hot midday dinner. There was also a striking improvement in complexions and complete disappearance of minor cutaneous troubles. Menzies

finds no evidence of general food shortage among London children but some want of ingredients essential to health which are not easily obtained in the winter months.

Immunologic Problems of Diphtheria

At a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland the president, Dr. R. A. Q. O'Meara, delivered an address entitled "A Critical Consideration of Immunological Problems with Special Reference to Diphtheria." He contrasted the early results of Roux, Martin and Chaillon in Paris in 1894 with those of today. There was evidence that diphtheria in Paris was then associated with the gravis type of bacillus. The mortality in nonlaryngeal cases without antitoxin treatment was over 30 per cent. Antitoxin treatment brought the figure down to 12.4 per cent. In the Cork Street Fever Hospital, Dublin, the mortality in a comparable group of actively treated cases in 1936, 1937 and 1938 was respectively 17.4, 10.5 and 11 per cent. The dose in any case of the early experiment did not exceed 8,500 units and was probably not more than 5,000. Against this, doses of 120,000 units were given in severe cases today. The conclusion appeared to be that there had been no improvement in the treatment of the toxemia of diphtheria since the introduction of antitoxin and that, unit for unit, modern antitoxin was less potent than that originally employed. The principles guiding the development of antitoxin in the interval had been mainly directed toward purification so as to ensure the maximum number of units in the minimum volume, while the study of clinical efficiency had been relegated to a minor position. Diphtheria and other forms of prophylaxis were also suffering from the making of the avoidance of reaction the first criterion of an immunizing agent. The immunologist had been dazzled by the achievements of the chemist in isolating fractions of the organism which had antigenic properties and could be injected without causing reaction. But Pasteur and other pioneers appeared to show that in order to get solid immunity against the causal organism it was necessary to use something close to the whole organism and not a fraction of it. The modern tendency might lead to the abandonment of immunization as of no practical use.

In the discussion, Prof. J. W. Bigger said that serologists and immunologists showed a tendency to become too academic. Antitoxin had definitely reduced the mortality of both gravis and mitis infections, but the treatment had not improved to the extent that might have been expected. Dr. C. J. McSweeney said that the commercial antitoxin now used seemed to check the spread of membrane but had little if any effect on the undefined toxic factor which was responsible for the faucial edema. The hallmark of toxic diphtheria was "the bull neck." To combat this, reactions had to be faced. For a highly virulent organism something more potent than the existing antitoxin was required. Dr. A. R. Parsons thought it difficult to know how much antitoxin to give. Some years ago good results had been achieved by from 4,000 to 8,000 units, but today some workers said that doses should not exceed 100,000 units and were quite safe up to that. Was the present antitoxin not so good as that formerly used? Dr. J. McCann said that in the early days antitoxin was given subcutaneously with good results; now it was given intravenously or intramuscularly. Given in this way many units might be excreted from the blood and lost almost as soon as given. He suggested that antitoxin should be given subcutaneously as well as by the other routes.

In reply O'Meara said that his object had been to show that a problem existed, not to say that antitoxin should not be used in the treatment of diphtheria or that prophylactics should not be employed. In spite of many alleged improvements since the introduction of antitoxin, certain cases of severe diphtheria were not amenable to it. The existing prophylactics gave a high degree of immunity, but parents should not be told that the

child would certainly be protected. In immunology there had been too great a gap between laboratory and clinical work. It was important to use the whole organism and not isolated parts or products of it.

Vitamin C and Work

Nov. 18, 1939.

A recent paper by A. R. Ratsimamanga is devoted to the part vitamin C plays in work. It is well known that the human system does not synthesize the ascorbic acid that is needed in nutrition. He believes in the existence of a close connection between the metabolism of the glucides and the presence of vitamin C and demonstrates this connection by precise methods of dosage and by dietary studies on animals. The role of this vitamin is important also in the formation of glycolytic reserves, which are reduced whenever the supply of vitamin C is diminished. In animals at work there is a progressive decline of resistance to fatigue in keeping with the vitamin C impairment. Mortality and morbidity are higher and weight curves lower. Changes in the chemical processes are brought about by an increase in lactic acid and a decrease in creatine phosphoric acid. Vitamin C deficiency causes adrenal modifications such as cortical hypertrophy and a considerable decrease of the lipids of the zona fasciculata. Vitamin C deficiency is indicated by signs of adrenal insufficiency. All the facts justify the conclusion that vitamin C concentration necessary for the formation of the normal constitution of the adrenal cortex requires a certain adrenal hormone. The fact that this hormone ceases to function when a certain degree of deficiency has set in indicates that ascorbic acid is concerned in the action of this hormone.

The Place of Neurology in Medicine

P. M. Laignel-Lavastine was recently advanced to the professorship of the Clinique des maladies mentales et de l'encéphale in the Paris Faculty. Previously he held the chair of the history of medicine. Laignel-Lavastine delivered his inaugural lecture at the Asile Sainte Anne, in which he paid a tribute to Claude, whose successor he is. Claude, he said, demonstrated that in the majority of minor psychopathic conditions appropriate medication has its place. Hysteria has the power of dissociating certain functional activities, certain perceptions and representations and to fix them in such a fashion that they remain forgotten outside the consciousness, this functional trouble arousing no reaction in the patient. The hysterical person, like the schizophreniac, has lost his sense of reality. Claude took an interest in the reform of the instruction of psychiatry. Unfortunately, the diagnostic technic in psychiatry is often impaired by social or judicial prejudices and also by an exaggerated psychological solicitude. However, psychoscopy, conducted by means of questions and answers, ought not to be underrated, because the reactional coefficient of the patient, his constitution, his temperament and his character determine the nature of his actions.

Thoracic Wounds

In a recent session of the Académie de chirurgie, Desjardins and Clert presented conclusions drawn from twenty-four cases of thoracic wounds. Intervention is now generally recommended. According to the speakers, a distinction must be made between cases in which the thorax is open and those in which no pulmonary lesion is noted. If the lung is exposed, suture of the pulmonary tissue is indicated. If the wound is situated in the precordial region, intervention must be made without waiting for the appearance of cardiac signs or hemato-pericardium. Hemostasis is indispensable. If the base of the thorax is affected, prompt intervention is indicated. The local symptoms will decide whether the path of the projectile should be followed and the thorax attacked or if entry should be made by way of

the abdomen. However, it is better to open the thorax and to make an abdominal exploratory incision than to perform the delicate operation of thoracophrenolaparotomy. The sequel of an intervention in the thorax are usually uninvolved. If the hemothorax is not too abundant it is absorbed; suppuration is exceptional, but often a "secondary aggravation" of symptoms is encountered. An enormous collection of pleural serum develops, because of the presence of clots. Secondary pleurotomy is then indicated.

Aseptic Pus Therapy

The veterinary art at present contributes its experiences to medical therapeutics at the Académie de médecine. During the World War and in the years following more than 370,000 doses of aseptic pus derived from fixation abscesses in horses were employed for the treatment of infectious lymphangitides of horses and other quadrupeds. The active substances of aseptic pus seem to be connective tissue cells and the leukocytes. Miyagawa has shown that inert cells, injected parenterally in weak doses, stimulate the homologous cells of the organism. This effect, according to its authors, M. Belin and C. Belin, is multiple. Proteolysis and conjunctival and epidermic regeneration are clearly accelerated. Besides, aseptic pus has a general stimulating effect. According to observations in several infectious diseases, it heightens the processes of defense of the organism. Mackay, of Budapest, has applied aseptic pus therapy to extensive burns of the second degree. He made an injection of 2 cc. of pus diluted in a 1:8 ratio every two or three days and achieved noteworthy results.

Who Has Perfect Health?

Nov. 11, 1939.

Recent correspondence in the *Tidsskrift for den norske lægeforening*, the journal of the Norwegian Medical Association, has focused attention on a problem which is none the less engrossing for being more or less insoluble. It concerns the issue of certificates to the effect that so-and-so is perfectly healthy. It is the fashion now for every employer, public or private, to ask for such a certificate, which is expected to safeguard the employer from claims for compensation on behalf of employees whose health has broken down. It is the state which has set the example and the pace in this field, and now municipal authorities and private concerns have followed suit. Unfortunately, perfect health, like perfect beauty, is an ideal rather than a reality. And it is a poignant irony of modern life that, the greater the advances in medical science, the greater is the number of persons who deviate more or less from the ideal standards of health.

A generation ago the subjects of diabetes, tuberculosis, pernicious anemia, myxedema and many other diseases would not have been applicants for regular work for the simple reason that they would have been incapable of any work. But today there are thousands of diabetic individuals who, thanks to insulin, are much healthier and fitter for work than many an employee whose chief ailment is neurasthenia or insomnia. Then there are the thousands of ex-sanatorium patients whose working capacity has been completely restored by an artificial pneumothorax or some thoracoplastic operation but who cannot be certified as being physiologically and anatomically normal and healthy human beings. Writing on this subject, Dr. H. F. Høst urges the state and municipal authorities to take the lead by revising to a certain extent the high standard heretofore set for applicants for employment. What is needed more than anything else is a readjustment of certain fundamental conceptions in physiology and pathology. For at present prognosis lingers far too stiffly on the morbid anatomy of a bygone generation.

taking quite inadequate account of those vital processes which are so difficult to measure and which yet have the last say in the matter.

Should Public Hospital Diets Be Uniform?

It may seem strange that in Norway a question should arise concerning uniformity of hospital diets. But the inequality of man cannot be ignored, however perfect the doctrines of socialism may be in theory, and even in our public hospitals class distinctions are being made. Dr. Erling Rustung, who is attached to the University Hygiene Institute in Oslo, recently addressed a circular to the 136 hospitals mentioned in the 1938 year book of the Norwegian Medical Association asking the directors to answer several questions concerned with the board and lodging of their patients. He obtained replies from 111 hospitals, in sixty-eight of which it transpired that the board and lodging were the same for all. There were six hospitals in which, on the payment of an extra fee, the patient could have a ward to himself, but even in these cases there was only one dietary. In twenty-nine hospitals single bed wards and better food could be obtained on the payment of an extra charge. There were also eight hospitals with three dietaries at as many different prices.

In their replies to Dr. Rustung, several of the hospital directors commented on this problem of better food for richer patients. One of them wrote that the patient's food in a hospital is a part of his treatment and it is therefore monstrous to draw a dietetic distinction between poor and rich. There can be only one treatment, and that the best. But a few correspondents leavened their socialism with the reflection that the finances of a hospital may be aided by letting the rich pay comparatively big fees in return for certain dietetic privileges. In most cases, however, it is clear that a uniform dietetic standard is that which is most in vogue in Norway and that which is approved of by most of the authorities responsible for hospital administration.

The Norwegian Radium Hospital

Only a few years old, the Norwegian Radium Hospital near Oslo has already become a national institution greatly appreciated by the public. It is to a large extent the child of one man, Dr. S. A. Heyerdahl, who in February 1938 retired as its senior medical officer. His place in this respect has been taken by Dr. Rolf Bull Engelstad, with whose publications on radiologic subjects many outside Norway are familiar. The last annual report of this institution has recently been published and covers the year 1938. More than half the space in this report is devoted to a monotonous tabulation of all the patients who were treated in 1938. The reader is left with the impression of having lost sight of the wood because of the wealth of individual trees in it. Elsewhere in the report there are many items of interest.

In the year under review, 5,607 patients underwent polyclinic examination, only 340 being new patients. In the same period the number of patients receiving treatment was 1,760, and the daily number of patients given resident treatment was on the average between eighty-five and eighty-six, the highest number in one day being ninety-four and the lowest number sixty-eight. The anesthesia induced in 151 cases was varied enough: ether narcosis in nineteen cases, spinal anesthesia in forty-two, local anesthesia in thirty and evipal narcosis in forty-eight. It was noteworthy that there was only one chloroform narcosis. Changes in fashion are also noted in a table showing the operations performed. Here one finds electrocoagulation figuring in fifty-two cases, nineteen of which concerned cancer of the vulva and twelve cancer of the tongue. Exploratory laparotomies were performed in seven cases. The lack of information about late results and follow-up inquiries reflects the fact that this particular hospital is quite new.

BUDAPEST

Nov. 15, 1939.

Appeal of Medical Association to Minister of War

After the World War the Hungarian Medical Association made an appeal to the ministry of war as a result of which military surgeons were declared to be of the same rank and with the same pay as combatant officers. Soon, however, the ministry of war found a new grouping necessary and military surgeons were placed in a lower group. The medical profession did not protest against this setback and the active army surgeons accepted the situation obediently. The reserve physicians did not deem this important, since at that time there was no compulsory military service in Hungary and nobody thought there was any danger of a new war. The medical association has again appealed to the ministry of war requesting that physicians in military service be given equal rank with combatant officers. The appeal argues that physicians serving in public hospitals and in the army are indispensable, sharing in all the dangers of war. During the World War many physicians were wounded or killed. The appeal further requested that university professors, lecturers and readers as well as senior hospital physicians and chief physicians of the ambulatories be given adequate rank and pay according to their scientific abilities. At present there are many prominent men in the medical profession listed as subaltern officers in the military registry books. It is expected that the ministry will decide in favor of the physicians, in view of the fact that in almost all neighboring countries military surgeons are equal in rank and salary with combatant officers.

Professor Schaffer Is Dead

Charles Schaffer, retired professor and director of the Budapest Neurologic and Psychiatric Clinic, died in his seventy-fifth year. During his career there was no one more diligent and successful in research on the histology of the brain. He started his work in a laboratory fitted up with his own money in the hospital of the poorhouse; later he moved to Professor Lenhossék's anatomic institute. He was interested in private practice only so far as it seemed necessary in his investigations. In the field of histology of the nervous system his work attracted the attention of the whole scientific world. Professor Schaffer was the greatest of contemporary Hungarian medical scientists.

Marriages

MARVIN A. BLANTON JR., Union City, Tenn., to Miss Katharine Geraldine Martin of Staten Island, N. Y., October 21.

ORION O. FEASTER to DR. ANNETTE BIEKER, both of St. Petersburg, Fla., in Dunedin, November 9.

WILLIAM HUDSON BROOKS, Sardis, Miss., to Miss Grace Evelyn Taylor at Helena, Ark., October 29.

PETER ALEXANDER DROHOMER to Miss Harriett Perry Coley, both of Daytona Beach, Fla., October 24.

GEORGE C. CARLSON, Quitman, Miss., to Miss Christine Wooley of Memphis, Tenn., October 8.

KENNETH HARLAND COWDERY to Miss Dorothy Lois White, both of Warren, Ohio, November 4.

HAROLD JAMES RICKARD to Miss Constance Marcell Gardner, both of Philadelphia, November 8.

JAMES A. DICKSON, Cleveland, to Mrs. Consuelo Proudft of Macon, Ga., in November.

BLISS BARTLETT CLARK, New York, to Miss Carolyn Morse at Montclair, N. J., October 21.

LOUIS KOVITZ, Kansas City, Mo., to Miss Dorothy Allis of Los Angeles, November 23.

CHARLES S. CARTER, Bells, Texas, to Mrs. A. O. Belote of Denison, August 30.

JACK I. WOOLF to Miss Orien Levy, both of Dallas, Texas, September 10.

Deaths

Josiah Newhall Hall * Denver; Harvard Medical School, Boston, 1882; professor of medicine emeritus at the University of Colorado School of Medicine, died December 17 at 80 years of age of pneumonia and myocarditis. He was a member of the Judicial Council of the American Medical Association from June 1921 to June 1931; a member of the House of Delegates in 1903, again in 1906, serving until 1908, and from 1919 to 1921. After practicing in Sterling, Colo., 1883-1892, he moved to Denver. He was mayor of Sterling in 1888-1889. From 1897 to 1902 he was professor of therapeutics at the University of Colorado School of Medicine and professor of medicine at Gross Medical College and later at Denver and Gross Medical College, continuing at the university after the merger of the schools. Dr. Hall was president of the Colorado State Board of Medical Examiners in 1891, of the state board of health in 1903-1904, of the American Therapeutic Society in 1916-1917 and of the Colorado State Medical Society in 1900. He was a fellow of the American College of Physicians and a member of the American Clinical and Climatological Association. During the World War he served as major in the medical corps, first as chief of the medical service at Base Hospital, Camp Logan, Texas, and then as consultant in internal medicine to the base hospitals of the Southwest and Western cantonments. He was on the staffs of Mercy, Denver, St. Joseph's and St. Francis hospitals. In addition to articles on diseases of the heart and lungs, he was the author of "Borderline Diseases," published in 1915, and the section on gunshot wounds, burns and scalds in Peterson and Haines' "Text-Book of Legal Medicine and Toxicology." Quite recently he had published for private circulation his personal reminiscences of a busy and useful life. He was widely beloved as a sincere, earnest, capable physician, as a leader in establishing the ethics and the true tradition of medical service, and as a pioneer in the building of medicine in the West.

Thomas Rundle Neilson * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1880; emeritus professor of genito-urinary surgery at his alma mater, and formerly emeritus professor at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; member of the American Surgical Association and the American Urological Association; fellow of the American College of Surgeons; past president of the College of Physicians of Philadelphia; consulting surgeon to St. Christopher's Hospital for Children; for many years on the staff of the Episcopal Hospital; aged 81; died, October 25, at his home in Devon, Pa.

Dennis John McDonald, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1888; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; formerly adjunct professor of laryngology and rhinology, New York Polyclinic Medical School and Hospital; for many years a member of the board of education; laryngologist to the Misericordia Hospital; laryngologist and otologist to the Dominican Convent of Our Lady of Rosary, New York, and St. Agnes Convent, Sparkhill; aged 74; died, October 8.

John Wesley Hanner * Colonel, U. S. Army, retired Burlingame, Calif.; Vanderbilt University School of Medicine, Nashville, Tenn., 1901; entered the army as an assistant surgeon in 1902; was awarded the silver star and the distinguished service medal for service during the World War; rose through the various ranks to that of lieutenant colonel in 1917; retired in 1922 for disability in line of duty; by a special act of Congress dated June 21, 1930, was retired as a colonel; aged 62; died, October 1.

Albert Charles Moerke * Burlington, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1896; at one time secretary of the Des Moines County Medical Society; formerly member of the state board of health and of the state board of medical examiners; past president of the Iowa Society of Clinical Surgeons; chief of staff, Burlington Protestant Hospital; on the staff of the Mercy Hospital and St. Francis Hospital; aged 72; died, October 30, of carcinoma of the colon.

Henry Dietrich * Los Angeles; Rush Medical College, Chicago, 1898; emeritus professor of medicine (pediatrics), University of Southern California College of Medicine; member of the American Pediatric Society and member and past president of the American Academy of Pediatrics; aged 63; for many years chairman of the executive committee of the medical staff of the Children's Hospital, where he died, October 16, of coronary thrombosis.

Earle Rogers Whipple * Steelton, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; member of the House of Delegates of the American Medical Association in 1930; past president of the Dauphin County Medical Society and of the Harrisburg Academy of Medicine; aged 57; served on the staff of the Harrisburg Hospital, where he died, October 23, of hypertension and heart disease.

L. Edward Villiaume, Buffalo; University of Buffalo School of Medicine, 1903; past president of the Erie County Medical Society; member of the Medical Society of the State of New York; member and past president of the staff of the Mercy Hospital; aged 62; died, October 16, in the Strong Memorial Hospital, Rochester, N. Y., of a head injury received on a golf course about two months previously.

Thomas Richard McHugh * Los Angeles; University of Michigan Homeopathic Medical School, Ann Arbor, 1901; fellow of the American College of Surgeons; formerly assistant professor of surgery at the College of Medical Evangelists, Loma Linda; served during the World War; formerly on the staff of the Queen of Angels Hospital; aged 62; died, October 21.

Herman Trossbach, Bogota, N. J.; Long Island College Hospital, Brooklyn, 1907; member of the Medical Society of New Jersey; fellow of the American College of Physicians; past president of the Bergen County Medical Society; aged 53; on the staff of the Hackensack (N. J.) Hospital, where he died, October 1, of hypertension and chronic nephritis.

George Farragut Raynor, New York; New York Homeopathic Medical College and Hospital, 1900; clinical professor of medicine at his alma mater; served the Metropolitan Hospital in various capacities; associate editor of the *Journal of the American Institute of Homoeopathy*; aged 68; died, November 1, at the Flower Hospital of coronary thrombosis.

John Gailwey * San Francisco; University of California Medical Department, San Francisco, 1885; fellow of the American College of Surgeons; a founder and past president of St. Francis Hospital; formerly member of the board of regents of the University of California and a member of the city park commission; aged 76; died, October 16.

Emil Ries * Chicago; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1888; past president of the Jackson Park Branch of the Chicago Medical Society and of the Chicago Gynecological Society; member of the Central Association of Obstetricians and Gynecologists; aged 74; died, November 14, of coronary occlusion.

Frederick Herbert Baker, Worcester, Mass.; Harvard Medical School, Boston, 1893; member of the Massachusetts Medical Society; for many years medical examiner for the city; aged 72; formerly on the staffs of the Worcester City Hospital, St. Vincent Hospital and the Memorial Hospital, where he died, October 1, of pneumonia.

Etley Price Smith * Fairmont, W. Va.; Jefferson Medical College of Philadelphia, 1909; fellow of the American College of Surgeons; on the staff of the Cook Hospital; past president of the Marion County Medical Society; served during the World War; aged 57; died, October 18, in Saranac Lake, N. Y., of pulmonary tuberculosis.

Maurice Ralph Zentner, Trenton, N. J.; New York Homeopathic Medical College and Flower Hospital, 1932; member of the Medical Society of New Jersey and the American Society of Anesthetists; on the staff of the William McKinley Memorial Hospital; aged 33; died, October 30, in the University Hospital, Philadelphia.

John Edwin Musgrave, Excelsior Springs, Mo.; University Medical College of Kansas City, Mo., 1907; member of the Missouri State Medical Association; past president of the Clay County Medical Society; served during the World War; aged 61; died, October 28, in the Excelsior Springs Sanitarium.

James Michael Cassidy, West Springfield, Mass.; Georgetown University School of Medicine, Washington, D. C., 1929; member of the Massachusetts Medical Society; aged 35; died, October 4, of burns received when his chair caught fire from a cigaret which he had been smoking before he fell asleep.

Edwin Link Ellis * Maryville, Tenn.; University of Tennessee Medical Department, Nashville, 1903; University and Bellevue Hospital Medical College, New York, 1904; past president of the East Tennessee Medical Association; aged 62; died, October 22, in the Johns Hopkins Hospital, Baltimore.

Alfred Ervan Chesley * Lawrence, Mass.; University and Bellevue Hospital Medical College, New York, 1904; member of the New England Otological and Laryngological Society; for many years on the staff of the Lawrence General Hospital; aged 63; died, October 27, of cerebral hemorrhage.

Willard Ralph Starks, Chatham, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; member of the Medical Society of the State of New York; bank president; aged 73; died, October 6, in a hospital at Albany, of lymphosarcoma of the cervical glands.

August Benjamin Hromadka ♂ Santa Monica, Calif.; Northwestern University Medical School, Chicago, 1907; fellow of the American College of Surgeons; served during the World War; aged 59; vice president and on the staff of the Santa Monica Hospital, where he died, October 26.

Doris Ellen Johnson, Youngsville, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1934; member of the Medical Society of the State of Pennsylvania; aged 33; died, October 23, in the Warren (Pa.) General Hospital following an emergency operation for ectopic pregnancy.

William Charles Leary ♂ Springfield, Mass.; Bellevue Hospital Medical College, New York, 1894; in 1934 member of the House of Delegates of the American Medical Association; aged 70; on the staff of the Mercy Hospital, where he died, October 13, of acute leukemia.

William Frederick Reich, Milwaukee; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; member of the State Medical Society of Wisconsin; for many years school physician; aged 69; died, October 12.

James F. Blanchard, Newport, Vt.; University of Vermont College of Medicine, Burlington, 1887; member of the Vermont State Medical Society; formerly acting assistant surgeon in the U. S. Public Health Service; aged 77; died, October 16, of cerebral hemorrhage.

Walter Ernest Boyer, Williamsport, Pa.; Medico-Chirurgical College of Philadelphia, 1907; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 60; died, October 22, of acute coronary thrombosis.

David Louis McAninch, Lamartine, Pa.; Jefferson Medical College of Philadelphia, 1879; member of the Medical Society of the State of Pennsylvania; past president of the Clarion County Medical Society; aged 84; died, October 6, of carcinoma of the bladder.

Henry Clifford Gerrard, Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1912; served during the World War; aged 54; died, October 15, at the Veterans Administration Facility, Rutland Heights, of pulmonary tuberculosis.

George Aitken Stevenson, Albert Lea, Minn.; College of Physicians and Surgeons, Keokuk, Iowa, 1880; Rush Medical College, Chicago, 1889; aged 85; died, October 25, in St. Peter (Minn.) State Hospital of arteriosclerosis and bronchopneumonia.

Harry Leo Moskowitz ♂ New York; University and Bellevue Hospital Medical College, New York, 1912; on the staffs of the Beth Israel Hospital and the Jewish Maternity Hospital; aged 50; died, October 31, of carcinoma of the intestine.

Frank Joseph Weigand ♂ Richmond Hill, N. Y.; Long Island College Hospital, Brooklyn, 1900; fellow of the American College of Physicians; on the staff of the Jamaica (N. Y.) Hospital; aged 60; died, October 29, in an automobile accident.

Roy Struble Gibbs ♂ San Bernardino, Calif.; University of Southern California College of Medicine, Los Angeles, 1901; past president of the San Bernardino County Medical Society; aged 69; died, October 30, of arteriosclerotic heart disease.

William Sharp Cranford, Taylorsville, Miss.; Memphis (Tenn.) Hospital Medical College, 1900; aged 68; died, October 31, in the Veterans Administration Facility, Gulfport, of staphylococcal septicemia secondary to abscess of the left leg.

Charles Eugene Parker ♂ Sterling, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; on the staff of the Public Hospital; aged 69; died, October 23, of arteriosclerosis.

Anton Johnson Moe ♂ Sioux Falls, S. D.; Rush Medical College, Chicago, 1897; fellow of the American College of Surgeons; chief of staff of a hospital bearing his name; aged 71; died, October 18, of cardiac decompensation.

Ulysses Simpson Mullins, Atlantic, Iowa; Rush Medical College, Chicago, 1895; past president of the Cass County Medical Society; formerly treasurer of the medical staff of the Atlantic Hospital; aged 67; died, October 11.

M. Clifford Pardee, Brooklyn; New York Homeopathic Medical College and Hospital, New York, 1899; aged 71; died,

October 25, of osteomyelitis of the jaw bone due to radium and x-ray burns and carcinoma of the mouth.

Robert L. Casburn, Sumner, Miss.; Long Island College Hospital, Brooklyn, 1884; aged 82; died, October 3, at the Baptist Hospital, Memphis, Tenn., of uremia, hypertrophy of the prostate and chronic myocarditis.

Maurice A. Neufeld ♂ Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; formerly police surgeon; for many years on the staff of the Chester Hospital; aged 68; died, October 20.

Frank Neely, Pittsburgh; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; member of the Medical Society of the State of Pennsylvania; aged 85; died, October 19, of coronary occlusion.

Robert Jasper Skaife, Colfax, Wash.; Kansas City (Mo.) Medical College, 1902; member of the Washington State Medical Association; formerly county health officer; aged 77; died, October 29, of pernicious anemia.

Clement Willis Sparhawk, Salem, Mass.; Harvard Medical School, Boston, 1884; member of the Massachusetts Medical Society; aged 85; died, October 22, in Watertown of cerebral hemorrhage and arteriosclerosis.

Jules John Delambre, Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1902; served during the World War; aged 61; died, October 28, in Fresno of coronary occlusion.

Alexander C. Ewing, Los Angeles; Hospital College of Medicine, Louisville, Ky., 1876; member of the House of Delegates of the American Medical Association in 1903; aged 90; died, October 3, of senility.

David Brandley Plymire ♂ San Francisco; St. Louis College of Physicians and Surgeons, 1895; California Medical College, San Francisco, 1895; aged 70; was killed, October 15, when he fell down a 60 foot bank.

Malcolm Stalker, Walkerton, Ont., Canada; Trinity Medical College, Toronto, 1878; fellow of the American College of Surgeons; on the staff of the Bruce County General Hospital; aged 86; died, October 18.

Albert G. Huizinga Holmes ♂ Miami Beach, Fla.; Rush Medical College, Chicago, 1893; formerly member of the school board; aged 75; died, October 30, in the Jackson Memorial Hospital of coronary occlusion.

Carl Cutting Corson, Portland, Maine; Harvard Medical School, Boston, 1932; member of the Maine Medical Association; aged 33; on the staff of the Maine General Hospital, where he died, October 3.

Victor Rousseau, Maple Lake, Minn.; University of Minnesota Medical School, Minneapolis, 1905; member of the Minnesota State Medical Association; aged 67; died, October 15, of coronary thrombosis.

Francisco Leopoldo Abad Gonzales, Manila, P. I.; University of California Medical School, San Francisco, 1927; member of the Philippine Islands Medical Association; aged 45; died, October 7.

Henry Leo Doherty, Stoughton, Mass.; Harvard Medical School, Boston, 1920; member of the Massachusetts Medical Society; on the staff of the Norwood (Mass.) Hospital; aged 44; died, October 9.

Maurice Hirsch Grossberg ♂ Cleveland; Western Reserve University School of Medicine, Cleveland, 1922; on the staff of the Mount Sinai Hospital; aged 43; died, October 22, at University Heights.

Alvin Burkett Waite, Huntingdon, Pa.; Medico-Chirurgical College of Philadelphia, 1902; formerly medical director of the Pennsylvania Industrial School; aged 63; died, October 3, of lobar pneumonia.

Hubert Hawthorne London, Des Moines, Iowa; State University of Iowa College of Medicine, Iowa City, 1920; aged 46; died, October 3, in the Broadlawns General Hospital of gunshot wounds.

Adam Bert Fair, Ottumwa, Iowa; State University of Iowa College of Medicine, Iowa City, 1895; member of the Iowa State Medical Society; aged 68; died, October 21, of carcinoma of the prostate.

Hubert Haldane Lee Casselman, Chesterville, Ont., Canada; McGill University Faculty of Medicine, Montreal, 1920; aged 45; died, October 2, at the Royal Victoria Hospital, Montreal, Que.

John Gibbs Lovell, Spokane, Wash.; Northwestern University Medical School, Chicago, 1904; aged 60; died, October 13, in the Santa Monica (Calif.) Hospital of heart disease and hypertension.

DEATHS

JOUR. A. M. A.
DEC. 23, 1939

- Charles Worthington Vishno**, New Haven, Conn.; Yale University School of Medicine, New Haven, 1885; on the staff of the Grace Hospital; aged 78; died, October 2, of bronchopneumonia.
- James Blenkhorn**, Stoneham, Mass.; University of the City of New York Medical Department, 1893; member of the Massachusetts Medical Society; aged 75; died, October 8, of carcinoma.
- Bartholomew Charles Pasuth** ♂ Bridgeport, Conn.; University of Maryland School of Medicine, Baltimore, 1916; served during the World War; aged 48; died, October 6, of coronary occlusion.
- Benjamin Franklin Noland**, Bassett, Va.; College of Physicians and Surgeons, Baltimore, 1881; formerly member of the state legislature; aged 86; died, October 20, of angina pectoris.
- Charles N. Davis**, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; member of the American Laryngological Association; aged 78; died, October 21.
- Frank A. Maxwell**, Austin, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1881; University of Nashville Medical Department, 1882; aged 83; died in October.
- Owen Meredith Waller** ♂ Brooklyn; Howard University College of Medicine, Washington, D. C., 1903; formerly a clergyman; aged 71; died, October 12, of cerebral thrombosis.
- Roy John Boynton**, Miami, Fla.; College of Physicians and Surgeons, Boston, 1905; aged 58; died, October 21, in the Dade County Hospital of cerebral hemorrhage and hypertension.
- Madison McCarty McKee**, Bridgeville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1903; on the staff of the Canonsburg General Hospital; aged 62; died, October 9.
- Thomas C. Neece**, Walnut Ridge, Ark.; Kentucky School of Medicine, Louisville, 1894; member of the Arkansas Medical Society; aged 71; died, October 17, of cerebral hemorrhage.
- Walter John Daly**, Philadelphia; Medico-Chirurgical College of Philadelphia, 1909; served during the World War; police surgeon; aged 52; died, October 17, of coronary thrombosis.
- Kenneth Raymond Parmenter**, Colorado Springs, Colo.; Boston University School of Medicine, 1896; aged 65; died, October 16, in Sudbury, Mass., of carcinoma of the rectum.
- Preston Worley**, San Antonio, Texas; Gate City Medical College, Dallas, 1903; member of the State Medical Association of Texas; aged 67; died, October 8, in New York.
- Albert A. Ogle**, Indianapolis; Chicago Homeopathic Medical College, 1898; member of the Indiana State Medical Association; aged 71; died, October 31, of coronary occlusion.
- Lewis Edward Davis**, Centralia, Pa.; Medico-Chirurgical College of Philadelphia, 1900; member of the Medical Society of the State of Pennsylvania; aged 64; died, October 14.
- Ira Robertson Teitworth**, Kingston, Pa.; Medico-Chirurgical College of Philadelphia, 1904; on the staff of the Nesbitt Memorial Hospital; aged 62; died, October 21.
- Charles Otto Schoier**, Jasper, Ind.; University of Louisville (Ky.) Medical Department, 1921; aged 63; died, October 25, in the Daviess County Hospital, Washington.
- William Joseph Hutchinson**, San Antonio, Texas; University of Southern California School of Medicine, Los Angeles, 1909; aged 73; died, October 30, of tuberculosis.
- George M. Brockway** ♂ Phoenix, Ariz.; University of Buffalo School of Medicine, 1890; for many years on the staff of St. Joseph's Hospital; aged 75; died, October 17.
- Wilbur Martin Pearce** ♂ Baltimore; University of Pennsylvania Department of Medicine, Philadelphia, 1893; aged 72; died, October 5, of carcinoma of the right lung.
- Meleatus Bruce**, Richmonddville, N. Y.; Albany (N. Y.) Medical College, 1898; member of the Medical Society of the State of New York; aged 70; died, October 25.
- Willis Adam Turnbull**, Tampa, Fla.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; aged 71; died, October 23.
- Henry Martin McLaurine**, Lynnville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1876; aged 85; died, October 1, of bilateral bronchopneumonia.
- John A. Beck**, Salinas, Calif.; Hahnemann Hospital College of San Francisco, 1897; member of the California Medical Association; aged 78; died, October 28.
- Theodore Franklin Johnson**, Perry, Iowa; Homeopathic Hospital College, Cleveland, 1876; aged 90; died, October 10, of osteo-arthritis and bronchopneumonia.
- Charles F. Ryan**, Fletcher, Ohio; Medical College of Ohio, Cincinnati, 1885; member of the Ohio State Medical Association, aged 79; died, October 29, in Columbus.
- Howard Jay Westney**, Atlantic City, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1907; aged 54; died, October 18, of arteriosclerosis.
- Arne Wilbur Clouse**, Geneva, Pa.; Rush Medical College, Chicago, 1900; served during the World War; aged 67; died, October 30, of cerebral hemorrhage.
- Avery Constantine Wilkins**, Shreveport, La.; Eclectic Medical Institute, Cincinnati, 1896; aged 68; died, October 26, of malignancy of the biliary tract.
- Rose Marie Merrill-Hyde**, Miles City, Mont.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; aged 74; died, October 3.
- Alden Otis Davis**, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1897; aged 67; died, October 11, in the Allegheny General Hospital.
- Aaron D. Sanders**, Corsicana, Texas; Gate City Medical College, Dallas, 1907; aged 68; died, October 21, of cerebral hemorrhage and arteriosclerosis.
- George Adrien Poux**, Guys Mills, Pa.; Jefferson Medical College of Philadelphia, 1915; aged 45; died, October 24, in St. Luke's Hospital, St. Louis.
- James T. M. Lindsay**, Houston, Texas; Meharry Medical College, Nashville, Tenn., 1894; aged 76; died, October 5, in the Houston Negro Hospital.
- William Edward Conlan**, San Francisco; University of California Medical Department, San Francisco, 1886; aged 77; was found dead, October 20.
- Edwin C. Brinkerhoff** ♂ Bicknell, Utah; Washington University School of Medicine, St. Louis, 1928; aged 41; died, October 24, of uremia.
- George W. Fockler**, Delavan, Ill.; Jefferson Medical College of Philadelphia, 1887; aged 76; died, October 28, of carcinoma of the prostate.
- Edwin Harvey Durgin**, Cupertino, Calif.; Boston University School of Medicine, 1889; aged 75; died, October 14, of coronary occlusion.
- Franklin Schaufelberger**, Hastings, Neb.; Jefferson Medical College of Philadelphia, 1894; aged 72; died, October 9, of coronary occlusion.
- Francis M. Martin**, East St. Louis, Ill. (licensed in Indiana in 1898); aged 85; died, October 23, in Belleville of bronchopneumonia.
- Rufus Charles Harris** ♂ St. Louis; Missouri Medical College, St. Louis, 1898; aged 63; died, October 10, in St. Mary's Hospital.
- Margaret White Cutting**, Agnew, Calif.; University of California Medical Department, San Francisco, 1909; aged 60; died, October 8.
- Michael Baker**, Denver; Gross Medical College, Denver, 1889; formerly postmaster of Evergreen; aged 85; died, October 25.
- George R. Ford**, Trinidad, Colo.; Kansas City (Mo.) Hahnemann Medical College, 1905; aged 77; died, October 28.
- Frederick John Walker**, Wheatley, Ont., Canada; University of Toronto Faculty of Medicine, 1905; died, October 14.
- Edwin Forrest Moore**, Vista, Calif.; Kansas City (Mo.) Medical College, 1886; aged 83; died, October 13, in San Diego.
- Earl Leslie Bennett**, Long Beach, Calif.; Jefferson Medical College of Philadelphia, 1914; aged 54; died, October 12.
- Cicero Fain Peck**, Somerville, Ala.; Memphis (Tenn.) Hospital Medical College, 1890; aged 76; died, October 4.
- Ira Carleton Ratterree**, Los Angeles; College of Physicians and Surgeons, Little Rock, 1910; aged 53; died, October 17.
- William M. Lottridge**, Littleton, Ill.; Columbus Medical College, 1880; aged 89; died, October 21, of heart disease.
- Jacob Louis Brower** ♂ New York; Long Island College Hospital, Brooklyn, 1905; aged 66; died, October 15.
- John L. Bradley**, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1894; aged 70; died, October 14.
- Robert S. Magee**, Long Beach, Calif.; Kansas City (Mo.) Medical College, 1890; aged 78; died, October 14.
- John W. Barnes**, Cato, N. Y.; Chicago Homeopathic Medical College, 1887; aged 82; died, October 8.
- Joseph J. Stewart**, Lamar, Ark. (licensed in Arkansas in 1903); aged 83; died, October 15.

Bureau of Investigation

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Alkalade.—De Pree Co., Holland, Mich. Composition: Chiefly baking soda, sodium phosphate and citric and tartaric acids. Fraudulently represented to "alkalinize" the system, dispel fatigue and "lack of pep" and to be "safe and harmless."—[N. J. 29793; March 1939.]

Astone Tablets.—Astone Products Co., Lansdale, Pa. Composition: Essentially corn starch, sugar, and plant material, including ephedrine. Fraudulently represented as a remedy for asthma, bronchitis, chronic coughs, la grippe and whooping cough.—[N. J. 30009; May 1939.]

Barbetigo.—Barbetigo Co., Salt Lake City. Composition: Water and zinc sulfate (18.2 Gm. per hundred cubic centimeters). Fraudulently represented as a germicide and a remedy for pyorrhea, tonsillitis, athlete's foot and some other conditions.—[N. J. 30005; May 1939.]

Bromo-Ease.—Honoroff Laboratories, Inc., Chicago, and Better Products Co., Marion, Ind. Composition: Acetanilid (6.33 grains per ounce) and small amounts of caffeine, citric acid and baking soda. Fraudulently represented as giving relief in stomach disorders.—[N. J. 29798; March 1939.]

Gayola.—D. R. C. Devine, Philadelphia. Composition: Chiefly epsom salt, baking soda and tartaric acid, with small amounts of salicylic acid and aspirin. For indigestion, arthritis and neuritis. Fraudulent therapeutic claims.—[N. J. 29785; March 1939.]

Etola.—Aryan Herb-an-Tonics Co., Gary, Ind. Composition: Chiefly extracts of plant drugs including hydrastis, volatile oils, including sandalwood and cubeb, with balsam copaiba and water. Fraudulently represented to cure gonorrhea, stricture, prostate trouble, bladder infections and "weak manhood."—[N. J. 30015; May 1939.]

Effervescent Alkaline Tablets.—Honoroff Laboratories, Chicago. Composition: Chiefly baking soda, cream of tartar, citric acid, acetanilid (1.1 grains per tablet) and aspirin. Misbranded because amount or proportion of acetanilid not declared on label and because fraudulently represented to be a remedy for rheumatism.—[N. J. 29798; March 1939.]

Effervescent for Headaches.—Honoroff Laboratories, Inc., Chicago, and Better Products Co., Marion, Ind. Composition: 14.24 to 14.91 grains of acetanilid per ounce in different consignments. Declared adulterated and misbranded because of false labeling of acetanilid content.—[N. J. 29798; March 1939.]

George's Compound.—Nick A. George, Casper, Wyo. Composition: Essentially sodium salicylate, extracts of plant drugs (including hops), sugar and water. Fraudulently represented as virtually a cure-all.—[N. J. 29781; March 1939.]

Hessel's Oil.—Vita Laboratories, Philadelphia. Composition: Essentially peppermint oil. Fraudulently represented as a remedy for asthma, diarrhea, hay fever, heart trouble, paralytic stroke and many other conditions.—[N. J. 30004; May 1939.]

Hetone.—Astone Products Co., Lansdale, Pa. Composition: Chiefly boric acid, ephedrine, and a small amount of chlorbutanol dissolved in water. For hay fever, catarrh, sinus trouble, bloodshot, smarting or watery eyes, etc. Fraudulent therapeutic claims.—[N. J. 30009; May 1939.]

Juvenol.—Himalayan Research Laboratories, Santa Monica, Calif. Composition: Essentially mineral oil (about 27 per cent) and fatty oils including castor oil. Declared adulterated because not wholly composed of vegetable oils as represented; misbranded because fraudulently represented as a "rejuvenator" and as a remedy for kidney stones, gallstones, obesity, rheumatism and some other disorders.—[N. J. 30002; May 1939.]

Kane's Gen-Sen.—Kane Laboratories, Portland, Ore. Composition: Essentially senna leaves, saffrair bark, licorice root and baking soda. Fraudulently represented as a "general tonic" and a remedy for kidney, liver, stomach and blood disorders.—[N. J. 30008; May 1939.]

McCane's (Dr.) Pep Tonic.—Queen Ann Co., Atlanta, Ga. Composition: Essentially an aqueous solution of iron chloride, epsom salt and sodium lactate, with small amounts of plant material and an unidentified alkaloid. For kidney, liver, stomach, blood and heart disorders, etc. Fraudulent therapeutic claims.—[N. J. 29794; March 1939.]

Trainer's Famous Oil.—Kane Laboratories, Portland, Ore. Composition: Chiefly gasoline, menthol, and oils of mustard and turpentine. Misbranded because falsely represented as a "rattlesnake oil" and because fraudulently exploited as useful in paralysis, deafness, rheumatism, pleurisy, hay fever, asthma, etc.—[N. J. 30006; May 1939.]

Correspondence

"TIME MARCHES ON"

To the Editor:—I had another check made on the facts in *Time's* "Misery Harbor" story of December 4. Since then you have published an editorial "Time Marches On" in the December 9 issue of *THE JOURNAL*. Your telegram will appear in the "Letters" column of the current issue of *Time* (December 18) with editorial comment. Your editorial is such an abusive attack that I want to answer it in detail.

It says:

The article in *Time* is mentioned here because it is replete with absolute misstatements of fact beyond anything of a similar character published in the field of medicine even in that periodical during recent years.

And then adds:

Indeed the article betrays a carelessness almost incomprehensible in a periodical which has in the past frequently gone to extended lengths to secure accuracy.

The "extended lengths" to which *Time* went to secure accuracy in the "Misery Harbor" story are as follows: Material on the situation in Cook County Hospital had been gathered since October 1938. Before *Time's* story was written, an editorial assistant personally interviewed in Chicago the principal persons involved. They were Dr. Karl A. Meyer (former medical superintendent of the hospital), Dr. Marshall Davison (present superintendent), Dr. Irving S. Cutter (chairman of the special committee which investigated the hospital in 1937). These were supplemented by telephone interviews with Dr. J. Roscoe Miller (assistant dean of Northwestern University Medical School, of which Dr. Irving S. Cutter is dean); Dr. Raymond W. McNally (chief of staff at Cook County Hospital and the hospital's representative at various committee meetings); an assistant in A. M. A. Education Secretary William D. Cutter's office; the secretary to Dr. Malcolm T. MacEachern (associate director of the American College of Surgeons and director of its hospital activities). In addition, we consulted, of course, the "Report of Committee on Survey of Cook County Hospital," September 1937, which outlines in detail the unfortunate conditions then prevailing at the hospital, newspaper articles on the situation (particularly those appearing in the *Chicago Tribune*) and *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. We did not, as you recommended in your editorial, secure the facts "merely by the use of the telephone." If we had gotten our facts by telephone from you, our story—judging by your editorial—would not have given a very enlightening account of what happened at Cook County Hospital. And incidentally, when one of our editorial assistants telephoned you in the fall of 1938 to discuss Cook County Hospital, you declined to discuss the matter and referred the question to Dr. Irving S. Cutter.

Now let's take up the eleven "errors" which you listed in your editorial. Italicized are the points as published by you (first the statement made by *Time* and then what you call the "correct statement"). My comment follows each:

1. "During the last four years Cook County Hospital has been a battleground for two warring medical factions." There has been no battle between two warring medical factions.

You leave the entirely false impression that there actually has been no real controversy. What would you call the situation? It has long been a matter of common knowledge. The *Chicago Tribune* (whose medical adviser, as you stated in your telegram, is Dr. Irving S. Cutter) quoted (Oct. 18, 1938) Dr. Meyer as saying in connection with the removal of the hospital from the approved list by the College of Surgeons:

The doctors at this hospital have taken this sandbagging just about as long as they are going to. There is less politics in the County Hospital than in any other institution in the city.

We'd be glad to have a comparative study made, banking our institution against any or all of them in the city. But they (American College of Surgeons and American Medical Association) won't tell us what they think is wrong—they just keep on making indirect attacks.

On Nov. 18, 1939, the *Tribune* said:

County commissioners, hospital officials and A. M. A. officials said the appointment will end the long controversy over administration of the county hospital.

2. "Last week a compromise ended the fight." There has been no compromise.

What do you call it when each side gets something and a settlement is reached? Early in 1939 the citizens' committee urged the ouster of Dr. Meyer but the Board of Commissioners of Cook County refused to comply. In May the committee made a concession: it suggested that Meyer be made superintendent of all county institutions and a new medical superintendent be appointed. This is what the board finally did, as well as adjusting a number of other differences.

3. "Dr. Meyer never required the hospital's army of interns to attend postgraduate classes or lectures." Lectures and conferences for interns have been held for at least ten years.

As put by you, *Time's* statement appears incorrect. It was not. Lectures have been held but Dr. Meyer never required the interns to attend, believing, as he did, that experience was what interns needed. The element of compulsion, not the existence of lectures, was the point of difference.

4. "The American Medical Association . . . believes that all interns should taper off into actual practice with at least eighty hours of medical lectures during internships." No specific number of hours of instruction has ever been mentioned, much less required, by the Council on Medical Education and Hospitals.

Our reporter was given to understand that the hospital has agreed to require eighty hours of lectures during eighteen months' internship. This would conform with the "Essentials in a Hospital Approved for Training Interns," set forth in *THE JOURNAL* (Aug. 26, 1939, p. 793): "At least a weekly period should be arranged for conducting clinical-pathological conferences, x-ray lectures or other special lectures or clinics for the interns."

5. "Consequently, four years ago, the A. M. A. dropped Cook County Hospital from its list of approved hospitals." Obviously the number of lecture hours was in no wise involved.

Considering that the American Medical Association sets a "weekly period" for lectures as standard for training interns, it is by no means obvious that the number of lecture hours is not involved. To *Time's* reporter the participants in the controversy spoke of it as a major issue.

6. "Over this point Cook County's Dr. Meyer and A. M. A.'s education secretary, Dr. Irving Samuel Cutter . . ." Dr. Irving S. Cutter is not the A. M. A.'s education secretary; he is Dean of Northwestern University School of Medicine.

We referred to the right man; I admit we gave him the wrong title. Dr. Irving S. Cutter, dean of Northwestern University Medical School, was chairman of the Committee on Survey of Cook County Hospital, has long been interested in the hospital's affairs, but his relative, Dr. William D. Cutter, is actually secretary of the A. M. A. Council on Medical Education and Hospitals. He too has been closely connected with Cook County Hospital. Both scrapped with Dr. Meyer. Hence the confusion and slip, which we are correcting in our "Letters" column this week.

7. ". . . thus automatically cutting off Dr. Meyer's supply of interns from topflight medical schools." At no time has the County Hospital failed to obtain interns from the four recognized medical schools of Chicago. No others are eligible for appointment.

Time would have stated the situation more precisely by saying "topflight interns from Chicago medical schools." Any promising medical school graduate who had a choice of internships would think twice before choosing a hospital without A. M. A. approval—for obvious reasons.

8. ". . . A. M. A. last spring brought public opinion to bear." At no time has the A. M. A. made any attempt to influence public opinion concerning the County Hospital. It has studiously refrained from comment upon the situation.

Public opinion was brought to bear by the citizens' committee, which represented the attitude of the A. M. A. (see

point 11). As to A. M. A. comments, have you forgotten the article in *THE JOURNAL* (Dec. 3, 1938, p. 2127) stating that the A. M. A. Council on Medical Education and Hospitals "found itself in fullest accord" with the recommendations of the Committee on Survey of Cook County Hospital and in which the Council urged the appointment of a physician experienced in hospital management as assistant to Warden Brigadier General Manus McCloskey? Also, has not the A. M. A. made various recommendations with respect to the hospital? Dr. Malcolm T. MacEachern (Associate Director of the American College of Surgeons) stated in the *Hospital Council Bulletin* (September 1938):

And finally the public is asking another question, "What is to be the future of the Cook County Hospital?" This remains undetermined but one can safely say that if the content of the Cutter report, backed up by recommendations made in reports submitted by the American College of Surgeons and the American Medical Association, were carried out to the fullest extent and in the truest spirit, without interference politically or otherwise, the County Hospital would attain the highest pinnacle of respect, success, and efficiency.

9. "An A. M. A.-inspired citizens' committee . . ." The A. M. A. had nothing whatever to do with the "Citizens' Committee" which was appointed by the Board of County Commissioners upon the recommendation of a committee of hospital experts previously employed by the County Board to investigate and report upon conditions at the County Hospital.

The A. M. A. Council on Medical Education and Hospitals (*THE JOURNAL*, Dec. 3, 1938, p. 2127) expressed approval of the report recommending that the citizens' committee be formed. Dr. Irving S. Cutter made himself "available" to the citizens' committee as adviser. The A. M. A. and the citizens' committee were spoken of interchangeably by the participants.

In 1938 hospital officials were reported seeking an A. M. A. survey of the hospital. The *Chicago Times* (Oct. 20, 1938) stated:

The American Medical Association will be asked to make a survey of the Cook County hospital, Dr. R. W. McNealy, president of the hospital medical staff, said yesterday. . . . Clayton F. Smith, president of the county board, said he favored Dr. McNealy's request to the A. M. A. . . .

And Dr. William D. Cutter (secretary of the A. M. A. Council on Medical Education and Hospitals) was quoted in the *Chicago Tribune* (Nov. 18, 1939) as saying:

The appointment of Dr. Davison is evidently an effort to fulfil the recommendation of the American Medical Association and the citizens' committee. No action (on the hospital's reinstatement) can be taken by the council until its meeting December 10.

10. Said committee " . . . hinted that the hospital might be reinstated on the A. M. A.'s list if a new director acceptable to the A. M. A. were chosen." As stated above, the Citizens' Committee had no connection whatever with the A. M. A. and therefore could not and did not claim to represent it.

Time did not say that the citizens' committee claimed to represent the A. M. A. But the committee hinted broadly, as appeared in the *Chicago American* (March 15, 1939):

Both Charles H. Schweppe, chairman of the committee and Dr. (W. D.) Cutter said replacement of Dr. Meyer by a medical head devoted full time to the hospital would help restore the institution to the accredited list.

11. "(2) Cook County was promised reinstatement on the A. M. A.'s list same time around Jan. 1; . . ." No such promise was given.

Yesterday, December 11, Cook County Hospital went back on A. M. A.'s approved list. If A. M. A. did not promise to restore the hospital to its approved list the coincidence is remarkable. But *Time* was not alone in finding that the hospital reorganization plan and A. M. A. approval were interwoven. Apparently most of the reporters in Chicago also found it out. Examples:

The *Chicago Times* (Nov. 19, 1939):

The A. M. A. announced, the Cook County Hospital will be returned to its list of hospitals approved for internship. The announcement followed appointment of Dr. Marshall Davison as medical director of the institution.

The *Chicago Tribune* (Nov. 18, 1939):

The American Medical Association soon will restore the Cook County Hospital to its list of hospitals approved for internship. This became certain yesterday with the county board's appointment of Dr. Marshall Davison to succeed Dr. Karl A. Meyer as hospital medical director.

The Chicago American (Nov. 17, 1939):

In announcing the appointment, Clayton F. Smith, president of the County Board, said it had the approval of the American Medical Association. Smith was hopeful that Dr. Davison could restore the hospital to the A. M. A.'s approved list, from which it was dropped a year ago.

Obviously, *Time* did not let A. M. A.'s cat out of the bag, but apparently you decided that you would like to bag a cat that has been running around free—and your method of doing so is to attack *Time*. As an unfair attack, I believe THE JOURNAL editorial goes "beyond anything of a similar character published even in that periodical during recent years."

MANFRED GOTTFRIED, New York.

Managing Editor of *Time*.

COMMENT.—1. *Time's* answer is to quote Karl Meyer and the Chicago Tribune as though they were infallible.

2. The Citizens' Committee, the Council and the College of Surgeons asked for the appointment of a "medical director." They got what they asked for.

3. Technically, *Time's* answer is correct, but its original statement conveyed the implication that there were no lectures, which was incorrect.

4. *Time's* answer is irrelevant.

5. Same as No. 4.

6. *Time* has admitted its error.

7. Same as No. 6.

8. The American Medical Association has at no time attempted to influence public opinion on this question. No statement about the Cook County Hospital situation has appeared in the editorial columns of THE JOURNAL; merely an official statement by the Council regarding the hospital's removal from the accredited list.

9. The fact that the Citizens' Committee arrived at the same conclusion as the Council surely does not justify the statement that the committee was "inspired" by the Council.

10. *Time* relies on a quotation from the Chicago American, March 15, 1939, which had no basis in fact.

11. The claim that the Council promised approval to the County Hospital is based on the fact that the hospital actually was approved. Such fallacious reasoning needs no further comment.—ED.

DOCTORS ON STAMPS

To the Editor:—Do you not feel that the opportunity is at hand to give a small measure of recognition to a group which has thus far been sadly neglected?

I refer to your editorial to the effect that two physicians are to be honored by an issue of postage stamps.

No one, I am sure, would wish to detract from the recognition and honors that Reed and Gorgas have received for their part in the yellow fever work. But some of us have long wondered, down through the forty years that has elapsed, why the acting assistant surgeons who served on the Yellow Fever Board, in comparison, have received such scant attention.

Agramonte, writing in 1915, stated that the definite promise was made when this board assembled that any credits or honors accruing from the board's labors would be shared by all alike. Comment on this aspect of the case is unnecessary.

Now, in all earnestness, Mr. Editor, might not that curtain which hangs before the eyes of justice be lifted a little so that occasionally it might be remembered that Lazear, Carroll and Agramonte were members of this board, all of whom were picked for their accomplishments and all of whom performed to their utmost?

Would it not be a gesture of human appreciation for the American Medical Association to suggest that one of these three receive this contemplated honor?

HARPER PEDDICORD, M.D., Redwood City, Calif.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

UNEXPLAINED FEVER AND AIR CONDITIONING

To the Editor:—Recently a patient consulted me because of recurrent bouts of unexplained fever. They occurred once every one or two months and came on around 6 p. m. and lasted until about 10 p. m. The maximum elevation of temperature has been 103 F. The next morning the patient feels completely well. Interesting enough is the fact that, at the time the patient has his bout of fever, fourteen or fifteen of his co-workers have a similar experience. All of these men are employed in an air conditioned office. Careful physical and laboratory examinations have been completely negative. Food poisoning cannot be a factor because most of these people take their meals at different places. Quinine given as a therapeutic test according to the Ross standard treatment for malaria has been of no value in preventing recurrences. I have been wondering whether it is not possible that, after these men have worked in an office at a temperature of 78 F., going abruptly into a temperature of around 100 might not in some way derange the mechanism that regulates the body temperature and produce this fever. If there are any available reports on such a possibility I would appreciate a reference.

Morgan W. Matthews, M.D., Shreveport, La.

ANSWER.—These occurrences of occasional but synchronous evening fevers in a group of workers in an air conditioned office are difficult to account for from known facts in the matter of the body temperature regulating mechanisms. Were all the fifteen workers in that office checked by competent physicians as carefully as this one patient or did they just report "feeling feverish" or "uncomfortably hot" the previous evening, after hearing the recital of this patient's evening experience on the following morning? The time 6-10 p. m. is in general the high peak of the daily body temperature curve. It is also a fact that the speed of adjustment to external temperature variations varies somewhat in apparently normal persons, the extremes being the rare individuals with a greatly reduced quantity of sweat glands. But it does not seem probable that all the fifteen workers in the office could fall in this one group. Were any of the workers free from the disturbance? And did the incidence of fever occur only on days of exceptionally high humidity? The fact that the fever appeared only once every thirty or sixty days shows clearly that the lag in the body temperature regulatory machinery in persons adjusted to 78 F., when passing suddenly into 100 F., cannot be the only controlling factor. This lag does occur. The degree and duration probably vary somewhat with the individual. In the writer, who has experienced it, the elevation of the body temperature never exceeded 1.5 degrees F. and never lasted as long as four hours. Air conditioning is now so common that if the incidents described were effects of merely a sudden change of environmental temperature from 78 F. to 100 F. there should be millions of such cases by this time. But it is a fact that such sudden temperature changes, in either direction, make one "feel" excessively hot or cold, more so than one can account for on the basis of actual changes in the body temperature. The vasomotor mechanism of the skin appears to adjust itself rather promptly to external temperature changes. The sweat secretion mechanism seems more variable and its efficiency is, of course, largely a matter of the humidity of the air. There is in all probability some lag in the adjustment to external temperature of the heat production in the skeletal musculature (variations in "tone").

EATING GLASS

To the Editor:—Would the inclusion of ground glass in ingested food be fatal to the individual who took it, or is it possible for the average person to chew up and swallow glass from an electric light bulb without injury, as is said to have occurred in a recent court trial?

M.D., Conn.

ANSWER.—The ingestion of glass may or may not be fatal. The nature and extent of the harm done, if any, depends on the size, shape and number of particles ingested and on the presence or absence of food in the mouth with the glass or in the gastrointestinal tract at the time the glass is swallowed. The danger lies in perforation of the wall of the stomach or the intestine and in acute or subacute gastro-enteritis. It would hardly be safe to say that the average person can chew up and swallow glass without suffering immediate injury, but it seems to be beyond question that some persons can do so. Dr. Walter S. Haines (Death from Pounded Glass and Other Mechanical Irritants, in Legal Medicine and Toxicology, by Many Specialists, ed. 2, vol. II, edited by Frederick Peterson, Walter S. Haines

and Ralph W. Webster, Philadelphia, W. B. Saunders Company, 1923, pp. 888-897) reported a case in which "a professional glass eater," in the presence of Dr. Haines and of Dr. E. F. Ingals, ate half a dozen 6 inch test tubes, two good sized lamp chimneys, an ordinary 4 ounce medicine bottle, two pieces of window glass, each 4 inches square, and three slips of colored glass each 1 inch wide and 3 inches long, biting the glass off the pieces offered him, chewing it up, and swallowing it much as if it had been an ordinary article of food. The glass eater had eaten a hearty meal before submitting to the test, as was his custom before each exhibition. He was kept under observation for several hours after eating the articles named but at no time did he show any unfavorable symptoms. He died, however, two or three years later, from a subacute gastro-enteritis, presumably, Dr. Haines says, from the irritation produced by his long continued glass eating. There are other well authenticated reports of similar purport.

ATTACKS OF ABDOMINAL CRAMPS

To the Editor:—A white man 33 years of age is in comfortable financial and social status and is in a profession that does not require physical activity but does entail great mental strain. He was in his usual state of health until seven years ago, when he sustained a "contused" right kidney in an automobile accident. For several weeks following the accident he had red cells in the urine, but this cleared up under treatment. From then until three years ago he was well. At this time (three years ago) he began to have bouts of abdominal cramps, generalized and severe. These come on with a regularity and follow no dietary indiscretions, nor do they follow the ingestion of any particular foods, although they have a direct relationship to mental strain and worry. The pains last from eighteen to thirty-six hours and then pass away. At the peak of the pain, sedation is sometimes necessary. The attacks have become more frequent in the last year. He has been examined during the attacks by a competent surgeon who states that no surgical condition is present. The temperature, pulse, respiration and blood pressure are normal even during the attack, although there is a slight rise in blood pressure. The white count and the differential count are normal also. A complete gastrointestinal study including many x-ray plates reveals a retrocecal appendix and evidence of a spastic colon. Proctoscopic and sigmoidoscopic examinations as well as fecal examinations have yielded negative results. Can there be any relationship between the injury and these attacks? Will spastic colitis cause such a history? If we can assume such a diagnosis can you suggest a regimen which will cause relief? If the disease is spastic colitis, can you refer me to some literature on the condition?

M.D., Pennsylvania.

ANSWER.—The present trouble is probably not associated with the injury, although careful x-ray studies with intravenous pyelograms should be done. In a patient of this type functional disturbances of the colon are common and are capable of causing severe abdominal pain. It is unusual, however, for it to appear in isolated attacks, and the bowel function is usually disturbed. Before the diagnosis of spastic colitis is made, duodenal stasis must be considered as well as partial obstruction in the small intestine. These may not be discovered by fluoroscopic study except during the attack. It is also of great importance to note whether the pains are rhythmic. If the examinations fail to reveal any organic trouble, it seems fair to assume that the patient has a functional disturbance. In treatment it is necessary to have the complete confidence of the patient and suitable diet to relieve the spasticity of the colon. The chapter on irritable colon in Oxford Medicine gives valuable information and may be of help in this case.

FOLLICULITIS OF SCALP: DIFFERENTIAL DIAGNOSIS

To the Editor:—I have on several occasions had cases in which small "shot-like" places under the scalp were complained of which later seem to come to the surface and break down, discharging a small amount of puslike fluid. These elevations seem to be found on areas having some hair and seem to "shun" bald spots. There is considerable itching, but outside of that patients do not seem to complain. I have tried painting with iodine, silver nitrate and phenol, and while these substances give relief there are new crops of the elevations at other areas of the scalp. Will you also tell me the etiology of this condition? I have been unable to find it described in the books at my disposal.

M.D., Chicago.

ANSWER.—It is difficult to make an unequivocal diagnosis in this case without more definite information about the character of the individual lesions, the course of events once they appear and the final result of their presence. Several entities come to mind for consideration. Perifolliculitis capitis abscedens et suffodiens is characterized by nodules and abscesses occurring on the scalp and terminating in scars. The nodules may be up to the size of a walnut. They are solid or fluctuant, colorless, yellow or livid. The lesions may be connected by sinuses and are devoid of hair. They exude a thin pus that dries into crusts. X-rays, vaccines and a sulfur paste have been employed with benefit. It is doubtful whether this is the correct diagnosis, because mention is not made of resulting bald spots, nor do the lesions in this patient seem to be large enough, nor do they burrow.

Acne varioliformis or necrotica should be considered. This is characterized by the occurrence over the brow, scalp or other regions of discrete, exceedingly indolent, reddish brown, papulopustular, often umbilicated, lesions which become covered with crusts and eventually leave depressed, superficial scars resembling those of smallpox. There may be few or many lesions. There is commonly a well marked coincident seborrhea. Many of the lesions are traversed by lanugo hairs. The subjective sensations are slight; at times there is itching. The disease tends to recur and is exceedingly chronic in its course. The treatment is with antiseptic lotions or ointments containing ammoniated mercury, resorcinol, sulfur, mercury bichloride and staphylococcus toxoid. Since this entity affects nonhairy portions as well as hairy ones, it may not be the fitting diagnosis in this case.

Acne necrotica miliaris of the scalp, described by Lane and also by Montgomery, is a more likely diagnosis, a folliculitis affecting the scalp of adults. The pustules are minute and usually few. There are rarely more than three or four present at a given time. They are always situated in the hair follicle and are of yellowish tinge. They soon rupture or are scratched and become capped with a crust which is not infrequently hemorrhagic. The disorder is persistent, lasting indefinitely when untreated. It is accompanied by subjective sensations of variable degree. Often the itching is severe.

Some form of folliculitis is undoubtedly present. This probably is on a seborrheic basis. Mercurials such as metaphen 1:25,000 may be used locally even after no lesions remain. Bacteriophage has been used locally with benefit in some cases of folliculitis of the scalp.

LUENBACH-KOEPPE PREGNANCY TEST

To the Editor:—Would you please tell me of what value is the Luenbach-Koeppel test for pregnancy?

Hymel Fishkin, M.D., Creighton, Pa.

ANSWER.—The Visscher-Bowman test has been definitely discarded by even its original proponents. Because of the great difficulty in reading an end point the test must be considered of no great value, and it is recommended that it be not used in the interest of accuracy and scientific medicine. The Luenbach-Koeppel test is definitely a modification of the Visscher-Bowman test and therefore must be considered in the same category.

ULCERATIVE COLITIS AND PREGNANCY

To the Editor:—A woman, aged 36, who has had chronic ulcerative colitis for the past four years, is anxious to have another baby. She has had three normal spontaneous deliveries. The three children are in good health. She has had several complete and thorough work-ups and regimens of treatment by several capable physicians. On one occasion they isolated a specific micro-organism. However, this was never found again. On and off she has had spontaneous periods of relief, and then she would get recurrences. Her medical history is negative and she has no other sicknesses. In the past few months she has been treated by a proctologist for pruritus ani with relief. She is the nervous and active type. Is it advisable for her to become pregnant, and is there any contraindication?

M.D., New York.

ANSWER.—The problem of pregnancy and its association with the diseases known as chronic ulcerative colitis has been discussed in an article on this subject by J. Arnold Bargen, Calisto Jose Nunez and Robert D. Mussey in the *American Journal of Obstetrics and Gynecology* (38:146 [July] 1939). While no exact answer can be given to the question because of the fact that no one's experience with this combination of circumstances has been large, these authors have made an attempt to find the answer in a review of the case histories of seventeen women who had eighteen deliveries and four miscarriages. They found that nine of the patients who had active ulcerative colitis were improved after delivery. In five the symptoms of the disease became worse. Three of the patients who had miscarriages were improved. The disease started after delivery of one patient. In three the symptoms were unchanged and in one case after miscarriage the symptoms were unchanged. In general it can be said that the combination of circumstances, namely pregnancy in an individual with ulcerative colitis, while it can become serious, does not present unsurmountable difficulties. Why some should be improved after pregnancy is a question that has not been answered. The fact that some became much worse has led these authors to feel that it is probably best in cases of chronic ulcerative colitis to try to avoid pregnancy. If, however, pregnancy occurs, a number of patients have been carried through an uneventful pregnancy by careful management of the colitis. It would seem reasonable for women who have had the disease and who have become free from symptoms to consider freedom from symptoms for two years as a minimal time before becoming pregnant.

NO LOSS OF LIBIDO FROM HYPERTYREXIA
To the Editor:—A man of 65, with long-standing central nervous system syphilis, had to have a series of hypertyrexia treatments about six months ago for a neuritis. He states that his sexual power diminished abruptly following these treatments, in which the fever was induced by short wave diathermy. He insists that his erections were good and his libido normal prior to the treatments. Is this a common sequel of the short wave treatment or has the treatment probably nothing to do with the lost libido, considering the man's age and affliction?
M.D., California.

ANSWER.—There have been no cases reported in which properly administered fever therapy produced a loss of libido. Patients commonly carry on normal sex activity between their fever treatments. The fact that advancing age and neurosyphilis are both important causes of decreased sex power would seem to be sufficient explanation in this case.
The symptom of neuritis, for which the fever was administered, would suggest that the patient was showing an advance of the process prior to the hypertyrexia.

CHRONIC CYSTIC MASTITIS
To the Editor:—What form of glandular therapy is advocated for adenofibroma of the breast, diffuse and bilateral? This condition has been found in a woman aged 22. Can you tell me what she may expect should she become pregnant? Would the breast which seems to be entirely involved now start to function, or would the condition persist through pregnancy?
Thomas J. Murphy, M.D., Decatur, Ill.

ANSWER.—The diagnosis in this case is probably chronic cystic mastitis, or Schimmelbusch's disease. Generally no treatment is necessary because the only way to cure this condition is to remove the breasts. This surely is inadvisable for a 22 year old woman. In some cases during pregnancy the breasts enlarge considerably and hurt appreciably but in other instances only the physiologic enlargement and engorgement of the breasts take place. These breasts can function during the puerperium, that is secrete milk in spite of the disturbance.
Androgen may be tried. Testosterone propionate in doses of 10 to 25 mg. may be administered intramuscularly three times a week for four weeks. Sometimes there is relief from pain and some improvement in the condition of the breasts. Usually the relief is temporary and lasts only as long as treatment is carried out, but in some cases the relief persists even after all glandular treatment has been stopped.

NASAL SECRETION WHEN EATING
To the Editor:—A young man otherwise in good health complains of nasal secretion when eating and when exposed to cold weather. He is embarrassed over the necessity of using a handkerchief frequently. Advice in this problem will be appreciated.
M.D., Massachusetts.

ANSWER.—The symptoms described suggest the possibility of heat and cold sensitivity as a cause of the trouble. Cold sensitivity is more common than heat sensitivity as a cause of allergic symptoms. In many cases, however, this type of reaction to thermal changes is secondary to or associated with a true atopy to inhalants, foods or drugs. It would be advisable to investigate such a case completely from this point of view, including adequate tests for thermal sensitivity. Such tests will be found in any of the recent textbooks dealing with allergy.

ANTI-ANEMIC POTENCY OF LIVER AND AGE OF ANIMAL
To the Editor:—Is there any difference in the anti-anemic activity of the livers of young and adult animals? It would seem to me that the liver of adult animals that have had green fodder would be better for the patient than that of the milk fed young. I would appreciate this information, as the price of the two types of liver here is quite on economic factor with many people.
M.D., California.

ANSWER.—The anti-anemic activity of livers can be satisfactorily assayed only on patients with pernicious anemia and the errors of the method are considerable. No convincing reports have been found that the anti-anemic activity of the livers of young animals is superior to that of adult animals.

DIPHTHERIA IMMUNIZATION
To the Editor:—What kind of diphtheria inoculation is recommended for mass immunization of school children today? The literature is contradictory and confusing.
M.D., Montana.

ANSWER.—Three doses of plain diphtheria toxoid, 1 cc. each, injected subcutaneously three weeks apart is regarded as an efficient method for active immunization against diphtheria. Sometimes 0.5 cc. is given for the first dose.

Diphtheria toxoid, alum precipitated, in two doses of 1 cc. each injected subcutaneously with an interval of four weeks is given preference by some. Advantages in using this preparation are that (1) only two doses are injected and (2) in a certain proportion of individuals a single dose establishes immunity. Therefore if there is failure, for any reason, to complete the two dose treatment a number of those who received this first injection will probably be immunized. The alum tends to retard rapid absorption of the toxoid and consequently the antigenic response is more prolonged than when plain toxoid is administered.
The choice of procedure for mass protection of school children against diphtheria is usually determined by the department of health or the health officer.

SULFANILAMIDE FOR TYPHOID CARRIERS
To the Editor:—In Queries and Minor Notes (The Journal, Oct. 14, 1939, p. 1510) you discuss the use of sulfanilamide in the control of the typhoid carrier state and remark that the only reference in the literature up to this time seems to be the article of Bazin (Canad. M. A. J. 38:559 [June] 1938), who employed sulfanilamide for a biliary paratyphoid carrier. In view of the lack of published reports on the use of the drug in the typhoid carrier state, I should like to place on record the following observation:
The carrier studied was a woman aged 58, who in 1901 suffered on illness resembling typhoid, although it was not diagnosed as such at that time. From 1901 to 1936 she was at different times employed as cook, nursemaid and general housekeeper, and during this period at least three cases of typhoid are believed attributable to her. In 1936, on application for the position of cook in a large tuberculosis hospital, fecal specimens were secured from her, from which typhoid bacilli were cultured. Typhoid bacilli having also been demonstrated in specimens of bile aspirated from the duodenum, the carrier underwent cholecystectomy in 1936 in the hope of being cured of the carrier condition. The removal of a chronically inflamed gallbladder containing stones, and the appendix, both of which yielded typhoid bacilli on culture, failed to relieve the carrier condition. Subsequent positive cultures of duodenal contents, as well as feces, suggested that the infection was located in the biliary tract.
Through the courtesy of Dr. William S. McConnell, who undertook the medical supervision of the case, the carrier was admitted to the medical service of Strong Memorial Hospital, Rochester, N. Y., in March 1939 for treatment with sulfanilamide in an attempt to cure the carrier condition. The treatment and results are summarized in the accompanying table.

Observation Prior to, During and After the Administration of Sulfanilamide to a Chronic Biliary Typhoid Carrier

Date	Sulfanilamide Administered Orally, Gm.	Blood Level of Sulfanilamide, Mg. per 100 Cc.	Blood Studies			Cultures for B. Typhosus		Comment
			Red Cells, Mil-lions	Hemo-globin, Gm.	White Cells	Bile	Feces	
1936	+	+	
1937	+	
1938	+	
3/ 6/39	4.36	12.6	7,930	..	+	Admitted to the hospital
3/ 8/39	+	
3/ 9/39	+	
3/10/39	8	+	
3/11/39	8	12.8	8,550	..	+	
3/12/39	6	+

3/19/39	Maculopapular rash, left cheek
3/20/39	+	..	Discharged from hospital
5/ 8/39	+	
5/ 9/39	+	
5/10/39	+	

The drug seems to have been tolerated well, the only untoward effect being the development of reddish maculopapular lesions on the left cheek March 19; these disappeared in a few days. The adequacy of the dosage may best be judged by reference to the sulfanilamide blood levels, which suggest that a concentration of approximately 10 mg. per hundred cubic centimeters was maintained for several days. The bacteriologic examinations show that typhoid bacilli did not disappear from the duodenal contents or feces during or following treatment with sulfanilamide. Perhaps other individuals might prove more responsive, or perhaps more intensive treatment with sulfanilamide would produce the desired effect. The typhoid carrier state is sufficiently important to carriers and to health officials to warrant continued research into the possibility of medical cure.
Paul A. Lembcke, M.D., Albany, N. Y.
Epidemiologist, New York State Department of Health.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examination of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, December 16, page 2261.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, March 5. Sec., Dr. W. W. Council, Box 561, Juneau.

ARIZONA: Phoenix, Jan. 2-3. Sec., Dr. J. H. Patterson, 826 Security Building, Phoenix.

ARKANSAS: *Basic Science*. May or June. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock. *Medical*. Little Rock, June 6-7. Sec., Dr. D. L. Owens, Harrison.

CALIFORNIA: *Oral examination* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California), Los Angeles, Jan. 17. *Written examination*. Los Angeles, Feb. 26-29. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: *Endorsement*. Denver, Jan. 2. *Examination*. Denver, Jan. 3-5. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Basic Science*. New Haven, Feb. 10. Chairman, Dr. Charles M. Bakewell, State Board of Healing Arts, 1895 Yale Station, New Haven. *Medical*. Hartford, March 12-13. Sec., Dr. T. P. Murdock, 147 W. Main St., Meriden. *Homeopathic*. Derby, March 12-13. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: *Examination*. Dover, July 9-11. *Reciprocity*. Dover, July 16. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, April 22-23. *Medical*. Washington, May 13-14. Sec., Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Tampa, June 17-18. Sec., Dr. William M. Rowlett, Box 786, Tampa.

GEORGIA: Atlanta, June. Joint-Sec., Mr. R. C. Coleman, III State Capitol, Atlanta.

IDAHO: Boise, April 2. Dir., Bureau of Occupational Licenses, Mr. H. B. Whittlesey, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, Jan. 23-25. Acting Superintendent of Registration, Mr. Lucien A. File, Springfield.

INDIANA: Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science*. Des Moines, Jan. 9. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

MICHIGAN: Ann Arbor and Detroit, June 12-14. Sec., Dr. J. Earl McIntyre, 202-4 Hollister Bldg., Lansing.

MINNESOTA: *Basic Science*. Minneapolis, Jan. 2-3. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 16-18. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: *Reciprocity*. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity*. Helena, April 1. *Examination*. Helena, April 2-3. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEBRASKA: *Basic Science*. Omaha, Jan. 9-10. *Applications must be on file not later than Dec. 26*. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEVADA: *Reciprocity with oral examination*. Carson City, Feb. 5. Sec., Dr. Frederick M. Anderson, 215 N. Carson St., Carson City.

NEW HAMPSHIRE: Concord, March 14-15. Sec., Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 18-19. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, April 8-9. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 29-Feb. 1. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 2-3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OREGON: *Basic Science*. Portland, Feb. 24. *Applications must be on file not later than Feb. 7*. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: *Written*. Philadelphia, Jan. 2-4. *Bedside*. Philadelphia, Jan. 5-6. Dir., Bureau of Professional Licensing, Dr. James A. Newpher, Department of Public Instruction, 358 Education Bldg., Harrisburg.

PUERTO RICO: Santurce, March 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, Jan. 4-5. Sec., Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 16-17. Dir., Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TEXAS: June 20-22. Sec., Dr. T. J. Crowe, 918-20 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: *Basic Science*. Seattle, Jan. 11-12. *Medical*. Seattle, Jan. 15-17. Acting Dir., Mr. Dave S. Cohn, Olympia.

WISCONSIN: Madison, Jan. 9-11. Sec., Dr. E. C. Murphy, 314 E. Grand Ave., Eau Claire.

WYOMING: Cheyenne, Feb. 5. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

Iowa June Examination

Mr. H. W. Grefe, director, Iowa State Board of Medical Examiners, reports the written examination held at Iowa City, June 6-8, 1939. The examination covered eight subjects and included 100 questions. An average of 75 per cent was required to pass. Ninety-seven candidates were examined, ninety-five of whom passed and two failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1937) 79.6, 90.4,	(1939)*	84.3
State University of Iowa College of Medicine.....	(1938)	(1938)	77.9
	82.1, 84.3, (1939)* 77.9, 79.6, 80.3, 80.5, 80.8, 80.9, 81.3, 82, 82.3, 82.3, 82.3, 82.4, 82.4, 83.4, 83.6, 83.8, 84, 84, 84.1, 84.3, 84.6, 84.6, 84.6, 84.8, 84.8, 84.8, 85.1, 85.3, 85.3, 85.4, 85.5, 85.5, 85.5, 85.8, 85.9, 85.9, 85.9, 85.9, 86, 86.1, 86.3, 86.4, 86.6, 86.6, 86.8, 86.8, 87, 87, 87.1, 87.4, 87.4, 87.4, 87.5, 87.5, 87.8, 87.9, 88.1, 88.1, 88.1, 88.4, 88.4, 88.4, 88.5, 88.6, 88.9, 89.1, 89.1, 89.3, 89.4, 89.8, 89.8, 89.9, 89.9, 90, 90.3, 90.3, 90.3, 90.4, 90.4, 91.5, 91.6, 91.9		92.8
Creighton University School of Medicine..	(1937) 89.1,	(1938)	81.4
Medizinische Fakultät der Universität Wien..	(1917)* 77,	(1935)	81.4

School	FAILED	Year Grad.	Number Failed
State University of Iowa College of Medicine.....	(1939)		1
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin	(1936)		1

* Licenses withheld pending completion of internship.

New Mexico Endorsement Report

Dr. Le Grand Ward, secretary, New Mexico Board of Medical Examiners, reports twenty-six physicians licensed by endorsement October 10. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1939) N. B. M. Ex.		New York
Stanford University School of Medicine.....	(1936)		California
University of California Medical School.....	(1922)		California
University of Colorado School of Medicine.....	(1911)		Colorado
(1938) N. B. M. Ex.			
Yale University School of Medicine.....			New York
George Washington University.....			Maryland
Northwestern University.....			Colorado
Rush Medical College.....			New York
State University of Iowa.....			Iowa
University of Kansas.....			Kansas
University of Louisville Medical.....			Oklahoma
Washington University School of Medicine.....			New York
University of Nebraska College of Medicine.....			Nebraska
University of Oklahoma School of Medicine..	(1931), (1933)		Oklahoma
Jefferson Medical College of Philadelphia.....	(1918)		Penn.
Baylor Univ. College of Medicine.....	(1930), (1937), (1938)		Texas
University of Texas School of Medicine.....	(1927), (1937), (1938)		Texas
University of Bristol Faculty of Medicine.....	(1934)		New Jersey
Université de Genève Faculté de Médecine.....	(1935)		New York

Tennessee September Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held at Memphis, Sept. 27-28, 1939. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-one candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Wayne University College of Medicine.....	(1939)		87.5
St. Louis University School of Medicine.....	(1939)		87.1
University of Tennessee College of Medicine.....	(1939)		82.1, 82.9, 83, 83.3, 83.6, 83.8, 84.1, 84.4, 84.6, 85.3, 85.9, 86, 86.4, 86.8, 86.8, 87.4, 89.3, 90.1

Colorado October Examination

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, Oct. 4-6, 1939. The examination covered eight subjects and included sixty questions. An average of 75 per cent was required to pass. Ten candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Rush Medical College.....	(1938) 84.5,	(1939) 85,	87
Osteopaths	75, 77, 78, 78.5,	80, 81,	82

* Licensed to practice medicine and surgery.

Book Notices

Pulmonary Tuberculosis in Adults and Children. By James Alexander Miller, A.M., M.D., D.P.H., Professor of Clinical Medicine, College of Physicians and Surgeons, Columbia University, New York, and Arvid Wallgren, M.D., Head of the Children's Hospital, Gothenburg, Sweden. 10th. Price, \$3.50. Pp. 193, with illustrations. New York & Edinburgh: Thomas Nelson & Sons, 1939.

As pointed out in both prefaces of this book, the work is a "fusion" of two monographs, each of which was prepared for a current system of medicine. Naturally, there are imperfections in such an artificial union. Repetitious statements, slight incongruities and lack of liaison are therefore more or less unavoidable, irrespective of the recognized ability and standing of both authors. Perhaps the most important incongruity is that the "cart is before the horse" when the "adult part" is placed ahead of that devoted to "tuberculosis of childhood."

Taking up Dr. Wallgren's part first (the logical order) there is little to say in a way of criticism and much to praise in the clinical field. It represents largely an essence of his own numerous studies. With regard to morbidity he tends to emphasize his own observations—an incidence of about 80 per cent infection by 20 years of age—but does not mention the fact that certain sections of the world have a much lower incidence. The mortality is highest in the first year (5 per thousand) and decreases to 2 per thousand for the second year and then less and less each year until between 9 and 12 years it is 0.5 per thousand with a slight rise again in puberty. The type of micro-organism, the modes and routes of infection, and portals of entry are described correctly and clearly. A point not commonly appreciated is that an incubation period exists from three to nine weeks, with a majority between four and six weeks. A conservative position is taken with regard to the relation of allergy and immunity. Although they are usually linked together, "tuberculin sensitivity is not in all cases a proof of the existence of immunity and the absence of tuberculin sensitivity is not in all cases evidence of the absence of a specific acquired immunity." He is emphatic with regard to the protection afforded by an infection to subsequent superinfections and reinfections.

The tuberculin reaction (with methods and types) is well covered. The author points out that a positive reaction represents the presence of an infection and that the reaction may diminish or disappear in malignant forms of the disease, in certain associated diseases, during the incubation period of primary tuberculous infection and on rare occasions when no cause can be found.

In the primary infection attention is directed to an important feature, the "initial fever" beginning at the appearance of allergy and lasting one or two weeks. It may rise to from 39 to 40 C. (102.2 to 104 F.). While other workers claim only about 30 per cent of such "invasion fevers," he finds it more frequently.

Erythema nodosum is considered as a nonspecific effect of tuberculosis (and more rarely other conditions) but the fever that accompanies erythema nodosum is like the fever that usually follows the primary tuberculous infection. When fever is present under such circumstances, it is a part of the initial fever.

Other symptoms of first infection are drowsiness, fatigue, headache, expiratory stridor and "bilateral cough." The latter is usually due to pressure of lymph nodes on bronchi. The patients usually lose appetite and weight and become anemic. There is almost a complete absence of physical signs and almost a universal presence of x-ray shadows of lesions either in the parenchyma or in the lymph nodes. The sedimentation reaction is recommended as a sensitive indicator to control progress. Bacilli are found in the stomach contents of 78.6 per cent of infants and about 50 per cent of older children having tuberculosis, and the more recent the infection the higher the percentage of bacilli. The lesions begin as a nonspecific pneumonia, then a specific infiltration, and then encapsulation, caseation and calcification follow in turn. Calcification begins at about a year and continues for many years. The lesion gradually shrinks for many years, some lesions disappearing altogether.

The Ranke classification of tuberculosis according to three stages (which both authors have adopted), although it has many attractive features, is not accepted by everybody and is not used by the Diagnostic Standards Committee of the National Tuberculosis Association.

For the first stage of Ranke with the primary complex and secondary hematogenous dissemination, most pathologists will agree. But when the "secondary tuberculosis" following the primary is placed in the same category with a late miliary tuberculosis or "protracted multiform miliary tuberculosis" or following an "exogenous infection" it doesn't make for simplification—the only real motive for the use of such a classification in the absence of the real facts. There are many controversial points. In the last analysis it resolves itself into a question of whether the lesions are encapsulated (secondary) or become open (tertiary) into some of the bronchial, gastrointestinal or urinary channels. Thus far, however, there is no anatomic basis for distinguishing between the two, outside of a communication or lack of it, with the exterior through these main channels. It is an attempt to explain too many phenomena by one method of classification. There hasn't yet appeared a logical system or classification that will adequately explain all immunologic and pathologic phenomena at one time, let alone the attendant clinical phenomena.

The author's handling of diagnosis, prognosis and treatment reveals the touch of one who knows his field. He recommends rest treatment during the fever stage and until the sedimentation becomes normal. It is usually from four to six weeks after the fever has subsided. The child should then be allowed up for short intervals and gradually return to normal and school work; all the while the temperature and sedimentation rate are watched. The question of hospitalization is not only medical but also a social problem. Primary tuberculosis does not necessarily need hospitalization, but if the home conditions are poor it is indicated. Children who have benign lesions without cough may be treated as noninfectious. Children with ulcerative lesions should be treated as any other patient with open tuberculosis.

Dr. Miller's part of the book is well presented as to the text, but the reproductions of pathologic conditions are indistinct and many of the x-ray reproductions do not show the changes at all. Furthermore, they do not harmonize with those in the second part. Both should have been either positive or negative. The paragraphs on infection, allergy, immunity, pathogenesis and prevention are well done, but there is no need for two different descriptions under one cover, with varying emphasis here and there but in general paralleling each other.

The development of an immunity as a result of allergy is rationally presented as well as the dangers of a hyperallergy with large dosage. The attempt to visualize the disease as an evolutionary pathogenic process is also to be commended, but as with Dr. Wallgren's part there is a question whether the classification of tuberculosis into three stages is as simple as it is intended to be.

The tendency to reject the term "reinfection type" in the sense that an exogenous reinfection is more important than an endogenous progression is justified, but there does not seem to be any need for calling it "second and third stages."

From a clinical standpoint the three groups primary, pre-phthisical and phthisical is a firm step in an attempt to correlate pathologic, x-ray and clinical observations and is perhaps better than any grouping yet proposed, although not free from objections.

The rest of the work is about as well presented as could be condensed into such a chapter in a system of medicine. The symptoms, modern methods of following subclinical phases (red cell sedimentation, leukocytic index, stomach lavage) are down to date. The physical manifestations, clinical course, diagnosis, differential diagnosis, complications, prognosis and treatment are all drawn along a modernization of classic concepts in an excellent manner. The author points out the limitations of physical examination and the importance of the x-rays, but unfortunately does not give all the important features of x-ray appearance of early lesions, nor does he show many simple lesions so important for beginners. This is more or less excusable, however, because of a lack of space. The surgical methods are brief but well presented. The part on prevention, overlapping considerably with Dr. Wallgren's part, includes education, pasteurization of milk, clinics, preventoriums, public health nursing, hospitals, sanatoriums, surveys, rehabilitation centers and vaccination. Lastly there is emphasized the important fact that the general practitioner is in the driver's seat in finding

tuberculosis and should be made to realize his importance and at the same time be instructed in the modern means of case finding.

In spite of the imperfections, this "hybrid" textbook possesses genuine value, is interesting and easy to read, and is perhaps as good as any similar work in the English language today. It is especially to be recommended for students of tuberculosis.

Atlas clinique d'ophtalmoscopie photographique: Syndromes cliniques du fond de l'œil. (Clinical Atlas of Fundus Photographies.) Par Henri Thilé, médecin-chef du laboratoire d'ophtalmologie, et A. Couadon, correspondant national de la Société d'ophtalmologie de Paris. Cloth. Price, 280 francs. Pp. 193, with 202 illustrations. Paris: Masson & Cie 1933.

For the past ten years the authors have been collecting photographs of the fundus of the eye. From their collection of 2,000, 202 were selected for publication. The preface, written by Mawas, fails to give credit to many of those most actively engaged in the field of fundus photography. This volume, the third photographic atlas to be published in the world, must necessarily be subjected to comparison with the previous two, the one by Dimmer and Pillat and the other by Bedell. In the former the reproductions are excellent and show no disfiguring arc image, while the second consists of the actual photographs and includes a great number of stereoscopic illustrations with the arc image. In the atlas under discussion there are black carbon spots. Some of these are so small as to suggest artefacts. The volume is logically arranged into the normal fundi, traumatic changes in the choroid, retina and optic nerve, inflammations of the optic nerve, inflammatory changes in the choroid and retina, congenital alterations, degenerations of the retina, degenerations of the macular area, changes in myopia, separation of the retina, hypertensive disease, diabetic changes, detachment of the retina, angioid streaks, blood states, cyanosis, intracranial pressure and tumors. The concise clinical descriptions aid the student in appreciating the fundus changes; in fact, without them diagnosis would often be impossible, for the authors write into the pictures things that are not in the prints. Several of the illustrations are noteworthy. These include some macular changes, especially the one called gliosis, myopic fundi, retinal folds, albuminuric retinitis, diabetic retinitis, and that which the authors call "stase papillaire," commonly referred to in English literature as papilledema, or choked disk. Attention is especially drawn to the illustrations of von Hippel's disease, which are among the finest ever published. The volume reflects credit on the authors for their technical skill, their selection of cases and the beautiful way in which these have been presented. It is recommended to all students of clinical ophthalmoscopy, for, although it is written in French, an English diagnosis is printed beneath each picture. The publishers have used clean type and a high grade of paper.

Arbeit und Gesundheit: Sozialmedizinische Schriftenreihe aus dem Gebiete des Reichsarbeitsministeriums. Herausgegeben von Professor Dr. Martineck, Ministerialdirigent im Reichsarbeitsministerium. Heft 36: Die Endangitis obliterans. Von Dr. Hans Karl von Hasselbach, Oberarzt der Chirurgischen Universitätsklinik München. Paper. Price, 6.70 marks. Pp. 168, with one illustration. Leipzig: Georg Thieme, 1933.

This monograph on Buerger's disease is interesting for the American reader for two reasons. In the first place it contains an excellent review of the literature on the subject, although obviously the English and American papers must have been read in abstract because their subject matter is often misquoted. Second, it contains for the first time an attempt to evaluate service connected disability on the basis of 193 cases, the files of which the author received from the Military Compensation Board. The difficulties of passing judgment in cases which the author did not have an opportunity to examine are obvious. Nevertheless, interesting case histories are presented. In the opinion of the author, prolonged exposure to cold or trauma may act as sensitizing factors for a person whose vascular tree is already hypersensitive to injury. With this working hypothesis in mind he presents a vague and indecisive outline as to how to evaluate disability from Buerger's disease in its relation to military service. He acknowledges liability if the disease occurs for the first time during active service or shortly after the completion of active service, including all late sequelae and recurrences. Nothing new is offered in the line of treatment. If anything the monograph depicts our present ignorance of the etiology and logical treatment of the disease.

Public Speaking for Technical Men. By S. Marion Tucker. Cloth. Price, \$3. Pp. 397. New York & London: McGraw-Hill Book Company, Inc., 1933.

Now that there are innumerable scientific societies in every branch of scientific learning which hold regular meetings at which topics are freely discussed, it becomes almost incumbent on the scientist who wishes to make progress in his field to be able to present his work suitably to his colleagues, to defend his thesis in open discussion—in a word, to understand how to influence people. This does not depreciate in any way the scientific value of his work; it merely recognizes the fact that elucidation is necessary for comprehension.

There are, however, many aspects in a scientific presentation which are quite separate from presentation before other bodies. The book by S. Marion Tucker gives a great deal of useful information and advice but unfortunately includes a mass of irrelevant data planned primarily to make the book readable. There is much discussion on the proper use of the voice, on the appearance on the public platform, on the use of vocabulary, on a study of the audience and on similar topics. Because of the technic of presentation of this book it is twice too long, much too long indeed for the amount of time that the average scientist would be willing to give to a work of this character. In certain aspects of the subject there is some doubt as to the author's capacity to recommend. This applies particularly to the use of humor. There are few, if any, occasions when humor is needed before a technical audience by a technical speaker. If there is such an occasion, it must be quite spontaneous and apropos. The story of "Pat and Mike" for the purpose simply will not do. There is no audience that can be so coldly silent and disapproving as a technical audience which happens to feel that the speaker is not taking with sufficient seriousness the problem of the day.

Gynecologic Operations and Their Topographic-Anatomic Fundamentals. By Prof. Dr. Med. Heinrich Martius, Director of the University Women's Clinic, Göttingen. Authorized English translation under the editorial supervision of W. A. Newman Dorland, A.M., M.D., F.A.C.S., Diplomate of the American Board of Obstetrics and Gynecology. Cloth. Price, \$10. Pp. 486, with 404 illustrations. Chicago: S. B. Debour, Publishers, 1933.

This is an English translation of what has been considered the best book of its type. In translating Martius into English, nothing has been lost, the text having become more understandable for the average American. The drawings, diagrams, anatomic sketches and technical details are exactly the same as in the German original, with nothing having been omitted. A study of this book will make one familiar with the surgical anatomy, relations and technic for all gynecologic procedures. The operative work is described from the incision of the skin to closure. Particularly interesting is the study of the operations for repair of relaxations of the urethral sphincter and for the repairs of fistulas. All in all, this is the best textbook of gynecologic surgical technic that it has been the fortune of the reviewer to study. It is a book that should be in the hands of all serious students of gynecology as well as the occasional pelvic operator.

The Treatment of Rheumatism in General Practice. By W. S. C. Copeman, M.A., M.D., B.Ch., Physician in Charge, Dept. of Chronic Rheumatic Diseases, West London Hospital, London. Third edition. Cloth. Price, \$4. Pp. 276. Baltimore: William Wood & Company, 1932.

A chapter on gout, one on focal sepsis and details of new methods of treatment have been added to this edition. The reviewer, however, is unable to share the enthusiasm expressed by others for the book. It is notably lacking in that critical discrimination between modes of treatment which is so highly desirable at the present time. A considerable number of proprietary remedies is recommended, some of them fortunately practically unknown in this country, including Kia-uma, Amysal, Balmosa, Aspirodine, Alasil and Kalmopyrin. A chapter is devoted to colonic therapy, with no new evidence added as to its efficacy, if any. There is also a chapter on osteopathy as "nature cures" in which, as in previous editions, osteopathy is far too favorably considered. The author would do well to consult the report of the select committee of the house of lords on the Osteopaths Bill in 1935 in his own country. Although there is a definite need for a volume on therapy for the general practitioner, the hope that this one would be developed along sound lines has not been fulfilled.

Les occlusions artérielles aiguës des membres: Formes cliniques, indications, physiopathologiques et thérapeutiques. Par H. Halmovici, assistant à la Faculté de médecine de Marseille, Marseille. Préface du Pr J. Floucl. Paper. Price, 26 francs. Pp. 124. Paris: Masson & Cie, 1939.

As one of a group of surgical and medical monographs written as a review and instruction for the general practitioner, the author describes the acute arterial occlusions in general, the perversions of physiology, the symptoms, various clinical forms, the diagnosis, prognosis and treatment. This review is entirely up to date and its main conclusions can only be reemphasized; namely, the difficulty of differentiation between arterial embolism and thrombosis; the utmost urgency in the treatment of arterial occlusion; the transportation of all such cases to surgical centers, where experienced surgical help can be secured; the place of antispasmodics, procaine hydrochloride block, sympathectomy, embolectomy, arteriectomy and amputation in the various stages of arterial embolism. The presentation is brief, concise and quite didactic. The American reader would welcome a few illustrations and case reports. The teaching value of this monograph to students and the general practitioner is unquestionable.

The Natural History of Population. By Raymond Pearl. University of London Heath Clark Lectures 1937. Delivered at the London School of Hygiene and Tropical Medicine. Cloth. Price, \$3.50. Pp. 416, with 40 illustrations. New York: Oxford University Press, 1939.

In this book the author has collected and summarized the results of his studies of human reproduction and fertility as gathered over a long period of years, and their apparent effects on world population. Altogether the factual data are impressive, but the author also has not hesitated to express his personal views of the significance and implications of the observed facts. Regardless of the ultimate corroboration or disproval of Pearl's excursions into speculation, the facts presented alone are of great importance. This book may be considered as required reading for those who wish to speak authoritatively on problems of human reproductivity and population trends.

Maternal Care and Some Complications: The Principles of Antepartum, Intrapartum, and Postpartum Care and of the Management of Some Serious Complications. Approved by the American Committee on Maternal Welfare, Inc. Prepared by W. C. Dantworth, M.D., et al. F. L. Adair, M.D., editor. Cloth. Price, \$1.50. Pp. 194. Chicago, Illinois: University of Chicago Press, 1939.

This book is a combination of two books previously published under the names "Maternal Care" and "Maternal Care Complications." These books have been reviewed in *THE JOURNAL* (Oct. 16, 1937, p. 1301, and Oct. 1, 1938, p. 1322). It is worth emphasizing that if most general practitioners of this country would acquaint themselves with the contents of this book there would be a marked improvement in antepartum, intrapartum and postpartum care, with a consequent sudden and dramatic decrease in the maternal and fetal mortality and morbidity.

Diseases of the Ear, Nose and Throat: Principles and Practice of Otorhinolaryngology. By Francis L. Lederer, B.Sc., M.D., F.A.C.S., Professor and Head of the Department of Laryngology, Rhinology and Otology, University of Illinois College of Medicine, Chicago. Second edition. Cloth. Price, \$10. Pp. 840, with 781 illustrations. Philadelphia: F. A. Davis Company, 1939.

The first edition of this volume appeared last year. Now appears a revised edition with numerous corrections and additions, particularly in the field of anatomy and in the illustrative material. The work continues to be an exceedingly practical and useful volume, especially for medical students.

Nutrition and Diet in Health and Disease. By James S. McLester, M.D., Professor of Medicine, University of Alabama, Birmingham. Third edition. Cloth. Price, \$8. Pp. 838. Philadelphia & London: W. B. Saunders Company, 1939.

This is the third edition of the book, which appeared first in 1927 and was reprinted in 1931. The present volume has been entirely rewritten and newly printed. An occasional paragraph from the earlier editions has been retained. The present volume places most of its emphasis on physiology. There have been added a chapter on the feeding of infants written by Dr. P. C. Jeans and one on feeding of the surgical patient by Dr. Deau Lewis. Here is a scientific and practical work on nutrition, discussing each of the dietary constituents fully, concerning necessary normal nutrition, and finally devoting a chapter to the

various nutritional diseases as they affect special organs or systems of the body. A large appendix provides tabular data quite complete. In the individual chapters there are numerous menus and other information of great practical value in the development of dietary advice in the practice of medicine.

Attaining Womanhood: A Doctor Talks to Girls About Sex. By George W. Corner, M.D., Professor of Anatomy, The University of Rochester School of Medicine and Dentistry, Rochester, N. Y. Cloth. Price, \$1. Pp. 92, with 15 illustrations. New York & London: Harper & Brothers, 1939.

This is a companion volume to the author's book entitled "Attaining Manhood," recently published. It provides a brief discussion of the human reproductive system and the reproductive cycle, followed by considerations of sex attraction and sex conduct. It is a book which will be found somewhat advanced for younger girls but which will, at the same time, be exceedingly useful for parents who wish to discuss these matters suitably with their children.

A List of Schools of Nursing Meeting Minimum Requirements Set by Law in the Various States. [Correct to January 1, 1939.] Paper. Price, \$1.75. Pp. 34. New York: National League of Nursing Education, 1939.

This is the first complete list of schools which has been published since 1935. It includes most of the information about individual schools which appeared in the previous edition and contains also data about the type of hospital in which the school is located and other pertinent items concerning the work of the school.

Diseases of the Foot. By Emil D. W. Hauser, M.S., M.D., Assistant Professor of Bone and Joint Surgery, Northwestern University Medical School, Chicago. With a foreword by Sumner L. Koch, M.D. Cloth. Price, \$8. Pp. 472, with 263 illustrations. Philadelphia & London: W. B. Saunders Company, 1939.

This book on the foot is mostly concerned with the practical aspects of the care of the feet, including hygiene as well as the various diseases and deformities from which human beings suffer. The illustrations, which are numerous, add greatly to the value of the text, which is simple and direct. The author reflects here considerable experience both in this country and abroad, covering more than 2,000 cases seen in the author's private practice. While the volume is entitled "Diseases of the Foot," it is concerned equally with fractures and dislocations involving the foot and ankle. The work is one of the best monographs available on the subject with which it is concerned.

Diseases of the Skin. By Richard L. Sutton, M.D., Sc.D., LL.D., Professor of Dermatology, University of Kansas School of Medicine, Kansas City, and Richard L. Sutton Jr., A.M., M.D., L.R.C.P., Associate in Dermatology, University of Kansas School of Medicine. Tenth edition. Cloth. Price, \$15. Pp. 1549, with 1473 illustrations. St. Louis: C. V. Mosby Company, 1939.

The tenth edition of Sutton's well established textbook appears four years after the previous edition. The progress in dermatology in the intervening period has been considerable. Not only from the point of view of description of new entities but also from the establishment of new concepts, the various chapters of the book appear to include these discoveries. Moreover, there are ten color plates and 340 new illustrations. The authors point out that there have been a 100 per cent increment in the number of words and at least 7,000 bibliographic entries since the ninth edition. The book is marked by the authors' own opinions and observations. There are an excellent chapter on serologic diagnosis of syphilis and new material on the identification of the fungi. In their work the authors have consulted many other leaders in the field, so that this volume now constitutes one of the most timely, dependable works in the field that it concerns.

La recherche de la paternité par les groupes sanguins: Étude technique et juridique. Par Louis Christiaens. Préface du Pr Leclercq. Paper. Price, 26 francs. Pp. 108. Paris: Masson & Cie, 1939.

As the title indicates, this small volume is not another presentation covering the entire field of blood groups and other individual blood differences but is concerned principally with the application of blood tests for disputed parentage. Emphasis is placed on the legal aspects in civil and criminal court actions and on the standing of the matter in various countries, statistics being given on the number of court trials in which blood tests were introduced as evidence. Of interest is the discussion of

the possibility of applying Schiff's discovery that the appearance of group specific substances in secretions is governed by a single pair of genes. Also the tabulation of special cases in which conclusions can be drawn as to a child's parentage from the examination of the grandparents deserves mentioning. The book will serve less as a guide to medicolegal experts than to physicians and members of the legal profession, for whom it will provide informative reading. A few obvious errors in the formulas of table VII (lines 1 and 3), table IX (line 1) and in the last line of table X should be corrected.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Pharmacists: Liability for Substitution in Compounding Prescription.—In May 1936, in the course of treatment in the Wisconsin General Hospital at Madison, the plaintiff was found to be allergic to mercury. On a form that bore the name of the hospital, he was given a prescription reading as follows: "Calamine Lotion c Phenol (1%) Quantity as desired. Sig. Apply as directed." Six months later the defendant's wife had this prescription filled at a store kept by the defendant at Spooner, Wis. The defendant did not dispense the lotion prescribed but without notice to the wife substituted for it a commercial compound marketed as calazine lotion. He knew that calazine lotion contained mercury, but he did not know that it was to be used on a patient allergic to mercury.

When the lotion dispensed by the pharmacist was applied to the patient, new areas of inflammation appeared. The patient's family physician was thereupon consulted. Apparently he knew that the patient was allergic to mercury or was informed of it at that time, for he inquired of the defendant pharmacist whether the compound dispensed by him contained mercury. The pharmacist replied that it did not. On advice of the patient's family physician a more liberal application of the lotion was made. The defendant druggist, however, got word to the patient's physician later that the lotion did contain mercury but not in time to prevent the application that the physician had recommended. Such of it as had been applied was removed as speedily as possible, but the patient's body was blistered and for two months he was unable to wear clothing. He thereupon brought this suit, alleging negligence on the part of the defendant.

Instead of being called on to render a general verdict as to whether the defendant pharmacist had or had not been negligent and to determine the extent, if any, to which the plaintiff had been damaged, the jury was required to render a special verdict, answering several questions of fact propounded to it, leaving the question of negligence to be determined by the court as a matter of law on the basis of the jury's answers. The jury found from the evidence that the defendant pharmacist had failed to use proper care in filling the prescription and that the sickness and disability of the plaintiff was a natural and probable result of such negligence. It found, however, that the defendant could not reasonably have foreseen that injury or damage to the patient would probably follow from his failure to use proper care in filling the prescription. The plaintiff moved for a new trial.

The issue turned apparently on the finding of the jury that the defendant pharmacist could not reasonably have foreseen the injury or damage that would probably result from his failure to use proper care in filling the prescription. A negative answer by the jury to this question might be justified when only the filling of the prescription was concerned, said the trial court, but if it had considered that the plaintiff's family physician made specific inquiry of the defendant as to the presence of mercury in the lotion he had dispensed, it might have concluded that the defendant should have realized that the presence or absence of mercury was important. This matter, the trial court said, should have been submitted to the jury, either by way of question or by appropriate instruction, and this was not done. The court therefore granted a new trial and the defendant appealed to the Supreme Court of Wisconsin.

What the trial court said was held by the Supreme Court to justify fully the order for a new trial. It was clear that the defendant misrepresented a fact when he delivered to the plaintiff's wife a proprietary compound containing mercury, instead of calamine with phenol as described in the National Formulary. There was ample testimony that druggists are expected to fill prescriptions according to the National Formulary or the United States Pharmacopeia, unless the contrary is indicated. There was some testimony that variations from the standard formula were followed by local custom, but it was clear that if such a custom could ever be an excuse it was not so in the present case, for the prescription came from a distant hospital, where the prescribing physician could not be expected to know of local custom prevailing in the city where the prescription was filled. The patient's wife relied on the defendant's unspoken representation that the medicine dispensed was exactly what the physician at Madison had ordered. Later, when the defendant repeated the representation by telling the physician that there was no mercury in the lotion, she, as agent for her husband, the plaintiff, again relied on the truth of the representation. One who makes a representation of fact or law is liable for any bodily harm that results to another person from an act done by that other person, or by a third person, in reliance on the truth of the representation, if the person who makes that misrepresentation knows that his statement is false and intends to induce action, or should realize that it may induce action, by the other or by some third person which involves unreasonable risk of bodily harm. A pharmacist may have had reason to suppose that the medicine which he supplied was just as good as what the physician prescribed, but it must be held that the risk of harm from the substitution without informing the purchaser outweighs any possible utility that the substitution may have had. It is even more apparent that an unreasonable risk was involved in this case in misinforming the physician. In explanation of his falsely answering the inquiry made by the plaintiff's physician, the defendant pharmacist testified that he believed that it was his duty not to disclose to one physician the ingredients in a prescription written by another. The Supreme Court pointed out, however, that he could easily have refused to answer at all. Either of the defendant's acts, in the judgment of the Supreme Court, constituted actionable misrepresentation.

The circumstances of a pharmacist's calling demand the exercise of a high degree of care and skill, the highest degree consistent with the reasonable conduct of the business. The effect of a mistake may be swift and disastrous. There are many cases in which pharmacists have been held liable for injuries resulting from negligence in filling a prescription or supplying a remedy. In the present case the liability is more apparent than in most cases, because the substitution was deliberately made under the mistaken impression that the prescription could be changed in accordance with the pharmacist's judgment.

The order of the trial court granting a new trial was affirmed. —*Hoar v. Rasmussen (Wis.)*, 282 N. W. 652.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Phantom Limb: Its Origin and Its Relationship to Hallucinations of Psychotic States. A. Gallinek, New York.—p. 413.

Sodium Amytal in Dementia Praecox.—According to Harris and his colleagues, in some earlier studies it was found that the intravenous injection of a freshly prepared 10 per cent solution of sodium amytal in preanarcotic doses produced transient ameliorating effects on some psychotic patients. Since such an ameliorating response indicated that the disturbed cerebral functions of these patients could be influenced favorably by a chemical agent, this reaction to the intravenous injection of sodium amytal was compared with the subsequent therapeutic effect of insulin hypoglycemic shock and metrazol convulsant therapy. The preanarcotic doses of sodium amytal were given fifty-five patients with dementia praecox prior to insulin hypoglycemic therapy. Thirty patients gave an ameliorating response to the sodium amytal and twenty-three of these a favorable response to insulin hypoglycemic treatment. The remaining twenty-five patients did not give an ameliorating response to sodium amytal and sixteen of these failed to respond to insulin treatment. The response to the sodium amytal test appears to be of prognostic value in insulin hypoglycemic shock therapy. Further studies are indicated.

Irreversible or Hyperglycemic Insulin Coma.—Wortis and Lambert point out that irreversible or hyperglycemic insulin coma presents a typical picture consisting of a sustained high blood sugar (following intravenous dextrose), fever, rapid pulse and respiration and frequently fits, vomiting or diarrhea. It is a serious complication occurring not only in shock treatment but no doubt in the management of diabetes as well. It may result in death or in permanent cerebral damage, but psychiatric persons who recover often show dramatic improvement in their mental state. Hyperglycemic coma is probably due to a therapeutic coma that has been prolonged beyond an hour or an hour and a half. Such prolongation is often unintentionally allowed, because the presence of gastric retention makes termination by tube feeding ineffective. As a practical consequence coma should generally not be allowed to last more than an hour or an hour and a half, especially when patients tend to rouse slowly, and sugar should be given intravenously to all those who do not begin to rouse fifteen or twenty minutes after tube feeding. In the authors' three cases of irreversible coma intravenous dextrose and the transfusion of 500 cc. of citrated blood

appeared effective. It would appear that the whole blood contains substances, other than oxygen or sugar, essential for cerebral metabolism, which have been destroyed or depleted by protracted coma. The dramatic psychiatric improvement in certain cases following prolonged coma suggests that if a safe method for such prolongation could be devised, it would further extend the value of shock treatment.

Sulfanilamide and Meningitis.—Sappington and Favorite present twenty-two cases of various types of meningitis treated with sulfanilamide and review the 205 cases reported in the literature. The matter is viewed almost solely as a clinical experiment analogous to experimental work in animals in which the death or survival of the animal is the criterion of the success or failure of the therapy. This is feasible because of the almost certain fatal outcome of all forms of acute meningitis, so that recovery under sulfanilamide of any large group of cases may be reasonably attributed to the drug (except in meningococcal and gonococcal meningitis, in which recovery does occur at times and the therapeutic value of the drug must be correspondingly modified). No definite conclusions can be drawn as to the value of sulfanilamide in meningitis as an entity owing to the variation in results in the different types of meningeal infection. Final opinions cannot be given in most instances until more cases accumulate in the literature. However, it may be said that the value of sulfanilamide in beta hemolytic streptococcus meningitis has been established beyond dispute. A reduction of the mortality from 95 per cent and above to about 20 per cent speaks for itself. Infections due to *Streptococcus viridans*, the tubercle bacillus or the gonococcus treated with sulfanilamide are too few in number for appraisal. The results so far in influenzal meningeal infections are discouraging. In pneumococcal meningitis with its terrific mortality, the outcome, nine recoveries in thirty-nine cases, at least warrants further trial and seems to offer possibilities. There were eleven deaths in eighty-four cases of meningococcal meningitis, a mortality of only 13 per cent, which appears remarkable. However, Hoyme reports only a mortality of 16 per cent in serum treated cases, and as in many of the drug cases serum also was given, conclusions should be withheld. However, if results are equal, sulfanilamide seems preferable. The necessity for specific serums in addition to the drug, as suggested by experimental work, has yet to be proved. As satisfactory concentrations of the drug in the blood and spinal fluid are easily attained by the oral route, it might be better to do away with intrathecal treatment and avoid the possible irritating influence of spinal taps for drainage and injection purposes.

Increased Blood Pressure.—Williams and Harrison studied 100 patients with increased blood pressures. Persons displaying elevation of only the systolic pressure and individuals with acute or chronic glomerulonephritis have been excluded. Certain patients presenting unusual types of hypertension have been

deliberately included for illustrative purposes. All the patients have had complete histories and physical examinations, urinalyses, blood counts and determination of the nonprotein nitrogen of the blood, and other laboratory tests. After the observations of each patient had been summarized and tabulated an attempt was made to separate the cases into various syndromes. However, in the present state of inadequate knowledge such separation is not entirely justifiable. Although it has not been possible to distinguish with certainty between the underlying and the aggravating causes of hypertension, and although in many instances more than one factor has seemed to be of importance, most of the individuals have displayed one major condition which appeared to be the most significant cause of the increased blood pressure. By recognizing and treating the underlying and contributing factors much can be accomplished in the alleviation of the disorders which are characterized by hypertension. The authors' classification of hypertension into six groups is suggested as representing a working approach toward an etiologic concept of the disorder: 1. Hypertension of neurogenic origin may be due to psychogenic, medullary, increased intracranial pressure and reflex causes. 2. That due to endocrine causes can be initiated by pituitary, adrenal and ovarian disorders. 3. The causes of renal hypertension are acute and chronic glomerular nephritis, obstruction to urine flow, infection of the urinary tract, diseases of the renal arteries and renal tumors. 4. Hypercholesterolemia (renal atheroma) and gout (uric acid deposits in the kidneys) are causes of metabolic hypertension. 5. In this group the hypertension is brought about by congestive heart failure. 6. The sixth classification includes mixed and unclassified causes of hypertension. No attempt has been made to distinguish between underlying and aggravating causes of hypertension. Thus, glomerular nephritis is clearly an underlying cause, while mental stress and strain is in all probability an aggravating or precipitating cause. Many of the conditions which have been listed seem to produce hypertension only when they occur in predisposed subjects. However, until more is known about this question it seems wise to include in an etiologic classification all factors which seem to produce hypertension, even though they may not initiate the disorder but serve only to intensify it. It makes little difference whether a given condition is underlying or aggravating, provided treatment directed toward it will produce benefit.

Neoprontosil for Chronic Ulcerative Colitis.—Brown and his co-workers used neoprontosil (oral) for the treatment of forty-eight patients with chronic ulcerative colitis. For further evaluation of the drug twenty-nine of these patients were treated with neoprontosil alone (group A). The remaining nineteen were given serum or vaccine in conjunction with neoprontosil (group B). In 44.8 per cent of the patients in group A the clinical results were considered excellent, in 44.8 per cent the results were fair and failure of treatment or poor results occurred in only 10 per cent. Analysis indicates that in 42 per cent of the patients in group B the results were excellent, whereas in 32 per cent they were fair and the treatment failed or poor results occurred in 26 per cent of this group. The authors state that the clinical response to neoprontosil is not predictable on the basis of the amount of intestine involved by the disease so long as its destruction is not too great. Obviously, all that any drug can be expected to accomplish is the control of symptoms that are due to active infection; those symptoms which result from altered function of a deformed intestine must be expected to continue to cause disturbances. If neoprontosil is used early in the course of chronic ulcerative colitis it seems that the maximal effect from the drug will be obtained. The prompt improvement of these lesions which has occurred so frequently and uniformly after the use of neoprontosil, the authors believe, justifies the conclusion that the drug is of definite benefit in this disease. However, the tendency of the disease to recur must be appreciated fully. Therefore they continued to give intermittent courses of treatment even when the disease has been symptomatically and objectively inactive for some months. The lack of toxic manifestations associated with the use of neoprontosil in general makes it especially adaptable to the treatment of chronic ulcerative colitis.

Classification of Essential Hypertension.—In an attempt to classify the contributing causes of essential hypertension, Schroeder and Steele review the 218 cases encountered at their hospital during the last ten years. At present ninety of the patients are dead, there is no information about eleven and 117 are living. Of the latter, 114 continue to be observed. All were referred as having typical "essential" hypertension and either exhibit or have exhibited elevation of diastolic pressure without failure of renal function. In most cases the time of the onset of hypertension is known within two years. Although essential hypertension has been regarded as a primary disease, the question is raised again whether it is not merely a syndrome common to a number of maladies. If so, some or all of the contributing mechanisms (renal disease, disorders of the nervous system, endocrine dysfunction and vascular disease) would be better understood if viewed in association with coexistent disturbances. The adoption of this attitude has been useful in understanding and in classifying cases in which hypertension has been considered essential and in which the underlying abnormal processes of the four systems set forth have been unsuspected. 1. Renal disease can be regarded as causally related to hypertension only in cases in which the diastolic pressure has fallen after a diseased kidney has been removed. Certain renal abnormalities seem to occasion hypertension, although they occur also in its absence. The condition is designated "renal hypertension with failure." In these patients a rapid course is not unusual (35 per cent), hemorrhagic and exudative lesions of the retina are common (65 per cent) and death from renal failure is often the outcome (76 per cent). 2. In the group suggesting derangement of certain functions of the nervous system (nervous hypertension) the arterial hypertension is benign. It occurs in younger persons and occasions few of the signs commonly associated with hypertension at this age. Changes in the retina, cardiac enlargement and failure of renal function are unusual. The lability of the blood pressure is noteworthy. The progress of the disease appears to be extremely slow even when the blood pressure is definitely elevated. The predominance of symptoms is of the nervous system. 3. It is still not clear whether dysfunction of the endocrines can be responsible for elevation of arterial pressure except in cases of pronounced endocrine dyscrasia (e. g., cases of Cushing's syndrome). However, endocrine dysfunction of less pronounced form is undoubtedly associated with essential hypertension in some cases, as it was present in 19 per cent of the authors' cases. They have called such a condition "endocrine hypertension." The patients in this category frequently complain of severe headache. In cases of "nongitrous thyrotoxic hypertension" the illness progresses rapidly, symptoms are severe, and hemorrhagic and exudative lesions are seen in the retina. If the hypertension begins at the menopause and after recovery from hyperthyroidism, it runs a benign course. While in ten of forty-three patients the course was consistent with the diagnosis of malignant hypertension, thirteen lived more than ten years. 4. Arterial hypertension is now believed to follow lesions of the blood vessels only when these lesions involve the arteries supplying the kidney. A constrictive mechanism of these arteries is believed to be operative when they are narrowed by arteriosclerosis. The course is usually benign (87 per cent),

arteriosclerosis of the vessels of the retina (but not retinitis) is common (97 per cent) and the terminal event is often apoplexy (64 per cent). Hypertension of this type is designated "arteriosclerotic hypertension." The authors believe that their study suggests that essential hypertension is not a primary disease. The fact that this diagnosis is made by exclusion should indicate multiple causes. Associated disturbances may be significant. A new classification is obvious. The present one cannot be regarded as more than tentative. However, it has been of advantage in facilitating diagnosis, in making prognosis more accurate and in indicating a more reasonable therapy. It is desirable that other means of differentiation be utilized to establish what is essential in this condition.

Structural Changes in Lungs of Drug Addicts.—During the last fifteen months Cole examined roentgenograms of the chest of 674 male drug addicts. In most instances they were taken after and in a few during the height of withdrawal symptoms. The status of the upper respiratory tract of 100 ambulatory drug addicts was determined. The investigation consisted of routine examinations of the sinuses by transillumination, and the sinuses of fifty were examined roentgenologically. The teeth, tonsils, pharynxes and nasal septums were inspected. In eighty other cases the changes were observed accidentally in the hospital after the development of acute illness. The 674 addicts were divided into two classes: those who entered the hospital voluntarily and those who were imprisoned for crimes not necessarily connected with the use of drugs. The youngest addict was 17 and the oldest 62 years of age; the average age was 39. The average duration of addiction was eighteen years, with a range from three months to thirty-nine years. Almost all the patients had taken more than one drug at some time. Heroin (diacetylmorphine) was the drug most commonly employed. Opium and its derivative morphine were next in order. Cocaine, contrary to popular conception, was used comparatively less than the others. Most of the drugs were taken subcutaneously. The addicts represented every stratum in the social scale. The withdrawal treatment, lasting six days, to which the addicts were subjected consisted of subcutaneous injections of progressively diminished quantities of morphine sulfate. The roentgenograms of the chest of only ninety-two of the 674 addicts, 13.5 per cent, were entirely normal. The commonest abnormality (207 cases) consisted of pulmonary changes characteristic of hypertrophic emphysema, i. e. voluminous lung fields, prominent hilar shadows, diffuse, increased vascular markings, obliteration of one or both costophrenic sinuses, and tenting and occasionally distortion of one or both diaphragmatic domes. Most of these patients used drugs for from fifteen to twenty years. Ninety-four patients merely showed signs of emphysema without generalized increase in pulmonary markings. Thirty-two addicts, according to whom there was only a short period of addiction, from three months to five years, showed increased markings with slight signs or no signs of emphysema. The remaining 249 addicts displayed, in addition to emphysema, some of the following changes: fibro-indurative tuberculosis of one or both apexes and occasionally of the subapical regions, minimal apical scarring, fibrocaceous pneumonic tuberculosis, calcified tuberculosis of one or both upper lobes, bronchiectasis, calcareous pleuritis (one case), interlobar effusion (one case) and emphysema bullosum (one case). About 30 per cent of the addicts with abnormal x-ray changes showed foci of infection of the upper part of the respiratory tract on routine physical examination. The author concurs with other workers that infections of the upper part of the respiratory tract play an important part in the production of structural changes in the lungs. However, in the 70 per cent of cases in which there were abnormal pulmonary changes but no apparent etiologic factor the age range itself (average 39 years) tends to explain these changes without an etiologic factor. Of the diseases which coexisted or developed during the period of incarceration, only tuberculosis is considered. Tuberculosis in all its forms constituted only 7 per cent. This is not without clinical significance. The experimental work of Brunelli and Luisida lends strong support to the conception that morphine sulfate when used in large doses over a prolonged period will produce definite structural pulmonary changes as well as alteration in the pulmonary circulation.

Scoliosis Following Empyema.—Because it was thought that scoliosis occasionally followed operation for empyema, Selig and Arnheim studied the records of sixty-five patients with nontuberculous empyema who were operated on at the Mount Sinai Hospital during the years 1932 to 1936 inclusive. An explanation was sought why some patients had persistent scoliosis after empyema while others, with apparently similar involvement, recovered without any permanent spinal deformity. The sixty-five patients examined from one to six years after operation for empyema are unselected and represent one third of all those operated on and they are a representative sample. Five had clinical evidence of scoliosis, but the curve of only two was severe. Of these two patients with chronic empyema beginning at the ages of 11 and of 2½ the primary curves were respectively 97 and 44 degrees. The curvatures were of contrasting types; the first had its convexity on the side of an extensive rib resection (thoracoplasty scoliosis); the second was concave on the side of the empyema, a typical postempyemic curve. Of the three patients presenting slight curves, two began to have chronic empyema at the age of 12 and multiple short rib resections had been performed. When observed eighteen years later, both had high dorsal curves, of 17 and 12 degrees respectively, with the concavity on the side of the empyema and compensatory dorsolumbar curves in the opposite direction. The remaining patient, a boy, began to have the chronic empyema at the age of 4. A partial thoracoplasty was done at 10 and when he was observed four years after the operation there was a curve of 9 degrees with the convexity on the diseased side. An analysis of the sixty cases in which empyema was not followed by lasting scoliosis shows that persistent scoliosis did not occur in any of the fifty-two in which there was acute empyema (with onset between less than 1 and more than 20 years of age) and in which wounds healed permanently in the mean time of four months or less. In the eight in which chronic empyema was present, scoliosis did not develop despite multiple operations, rib resections and excisions of the soft parts, whereas in the five in which persistent scoliosis did develop it followed thoracoplasties or multiple rib resections. Therefore the reasons for the appearance or nonappearance of persistent scoliosis following chronic empyema are not apparent, though clearly it does not follow acute empyema.

Multiple Myeloma.—Batts reports that the incidence of multiple myeloma at the University Hospital is at variance with its incidence as reported by other sources. Life insurance tables give its incidence as 0.03 per cent of all malignant growths or 3 per cent of all sarcomas of bone. In the American Registry of Bone Tumors, in proportion to osteogenic sarcoma it is in the ratio of approximately 1:12, and to Ewing's sarcoma of approximately 1:3. Of the 200 primary malignant tumors of bone seen at the University Hospital since 1925, forty have been diagnosed as multiple myeloma, an incidence of 20 per cent. The

Johns Hopkins Hospital reports an incidence of only 3 per cent of 400 sarcomas of bone. The forty cases of multiple myeloma discussed by the author were encountered in 298,546 admissions to the hospital, a ratio of 1:7,464. The average age of the patients in the series was 53 years. Multiple myeloma occurs almost twice as frequently in men as in women. Etiologically it is not related to trauma. Its chief symptom is pain, which may occur in any location and is not characteristic except that there is usually a single period of remission. Palpable soft tumors are found in half of the patients, usually on the skull or on the trunk. Pathologic fractures are common. Deformities of the thoracic cage and of the spine are not unusual. Paraplegia and nerve involvement referable to the spinal cord are frequent complications. Multiple myeloma occurs most frequently in the skull, spine, ribs and pelvis, in this order. X-ray examination shows multiple punched-out areas of osseous destruction with no evidence of osseous reaction. Secondary anemia and, in half of the cases, Bence Jones protein in the urine are present. The lesions show masses of round cells that resemble plasma cells, with little or no intercellular substance. At necropsy in about half of the cases the soft tissues, particularly the liver, spleen and kidneys, are invaded by myeloma. Arteriosclerotic nephropathy is present in most cases. Roentgen therapy gives relief from pain and prolongs life. Laminectomy and decompression of the spinal cord are indicated in cases of paraplegia due to multiple myeloma. Multiple myeloma is invariably fatal. The average duration of life from the onset of symptoms of the disease until death is about two and one half years. The longest survival on record in a proved case is fourteen years and four months. The prognosis is more favorable for relatively young patients and for those with initial solitary involvement, which usually became multiple before death.

Treatment of Male Hypogonadism with Mare's Serum.

—According to Kunstadter, it is now generally agreed that the anterior pituitary-like hormone from pregnancy urine and placenta are of definite value in the treatment of some types of hypogonadism and cryptorchidism. In view of the remarkable gonad stimulating properties of pregnant mare's serum (resembling in biologic effects those of the anterior lobe extract) in experimental and domestic animals and because of the convenient source of the hormone, it seemed justifiable to demonstrate the clinical effects of the hormone on patients with hypogonadism and cryptorchidism. Fourteen boys between the ages of 6½ and 14¼ years, who presented hypogonadism, cryptorchidism or both, were treated by the intramuscular administration of pregnant mare's serum. Definite improvement as evidenced by growth of the genitalia, the appearance of secondary sex characteristics or descent, partial or complete, of undescended testes occurred in eight, or 66½ per cent. Cryptorchidism was present in eleven of the fourteen patients, pseudocryptorchidism in four, and true cryptorchidism in seven. In the latter group complete descent of the testes occurred in one or both testes of three and partial descent in two patients. Two cryptorchids did not respond to treatment. There was no change in the distribution of fat or weight loss of any of the patients. It is believed that mare's serum is of definite value in the treatment of certain cases of hypogonadism and cryptorchidism. As yet the optimal effective dose has not been established, but the author believes

that from 50 to 100 rat units intramuscularly three times a week probably will be more effective than the 10 to 20 three times a week administered to his patients. With the higher dosage, results would probably be obtained in a shorter time.

Proteins of Extrathyroidal Origin in Myxedema.—Lerman and Salter say that the isolation of thyroxine by Kendall led to the conception that the prime function of the thyroid is the manufacture of this substance in toto. These studies, however, show that the simple incorporation of iodine into non-descript protein leads to thyroidal activity. When blood serum protein, in ammoniacal solution, is treated with compound solution of iodine according to the procedure of Wormald, within a short time there results an iodoprotein. The iodoprotein was administered to patients with athyreosis, and rapid and complete recovery occurred with proper dosage. Control patients who were given noniodinated serum protein showed no effect. In terms of total mass, the activity of the iodoprotein was about one fifth that of whole thyroid; in terms of iodine the activity was about one four hundredth. This discrepancy in activity is due partly to the presence of iodine in inert combination in the iodoprotein and in its derivatives. The low potency in terms of iodine is probably due also to the fact that the effective iodine-containing group is an iodothyronine derivative, which has lower potency than thyroxine. The iodinated protein can be fractionated by enzymes or alkaline hydrolysis into thyroxine-like (T) and into diiodotyrosine-like (D) fractions. The latter were inert; the former possessed all the activity present in the original iodoprotein. As with the enzymatic split products of thyroglobulin, the D fraction yielded no thyroxine-like amino acid after drastic treatment with hot barium hydroxide solution, whereas the T fraction yielded, under such treatment, material which resembled iodothyronine derivatives (related to thyroxine). The latter can likewise be recovered from the original iodoprotein by drastic alkaline hydrolysis without previous separation into component peptones. Such a procedure is the standard method for obtaining thyroxine from thyroglobulin. The observations reported here show that simple iodoprotein as well as its hydrolysates are effective in relieving human myxedema. This evidence that thyroidal activity can arise in a colloidal molecule through simple iodination throws some doubt on the prevailing concept that the thyroid gland manufactures thyroxine in toto and then builds it into a protein for storage. Perhaps in the iodinated colloid itself may be found the beginning of thyroidal activity.

Sulfanilamide in Gonococcal Endocarditis.—Fletcher and Scott state that four patients at the Johns Hopkins Hospital with gonococcal endocarditis received a seemingly adequate course of treatment with sulfanilamide. Three of them died and the diagnosis was subsequently corroborated at necropsy; the fourth patient recovered. After presenting detailed histories, the authors point out that the patient who recovered from her illness does not completely fulfil the most rigid criteria for establishing the presence of bacterial endocarditis. The regularity of the temperature curve, the cardiac symptoms in the presence of a positive blood culture and the nephritis make it seem likely that she suffered from a gonococcal endocarditis, probably involving the pulmonic valve. However, in view of the previous history of dyspnea on exertion, it is impossible to exclude the possibility that the patient may have had either a long-standing rheumatic lesion of the aortic valve or a patent ductus arteriosus, to explain the precordial murmurs, and that the present illness was merely a bacteremia without acute endocardial involvement. It is of interest that the patient showed two peaks of fever daily, a symptom noted by Horder and recently emphasized by Williams and Fletcher as common in

gonococcal endocarditis. Further, she showed the jaundice reported as complicating the latter disease. Finally, the patient had diffuse glomerular nephritis, which is frequently associated with gonococcal endocarditis. In evaluating the role of sulfanilamide in the improvement of this case, it should be recalled that recovery from proved gonococcal endocarditis itself has occurred following supportive therapy alone. The three patients who died despite treatment with sulfanilamide all received the drug more or less continuously for periods of from seven to fifty-four days. Blood levels of unacetylated sulfanilamide of 10 mg. or more per hundred cubic centimeters were attained, though not always constantly maintained, by each of the three patients. One of the patients died following a hemiplegia presumably due to a cerebral embolus. Another succumbed to myocardial failure apparently due to the hypertension accompanying a severe nephritis that complicated his endocarditis. In the valvular vegetation of neither of these patients were gonococci demonstrated. Since gonococci are notoriously difficult to cultivate, it cannot be stated with any certainty that no gonococci remained in the vegetations. It is possible, however, that the endocardial infection had been eradicated and that, had the processes complicating the endocarditis not occurred, these two patients might have survived. Treatment of a fourth patient with sulfanilamide proved ineffectual. Despite treatment with the drug over a period of twenty-five days and the attaining of blood levels of from 9.7 to 18.1 mg. per hundred cubic centimeters, viable gonococci were present in the endocardial vegetations at necropsy. Whether the responsible organism represented a strain of gonococcus peculiarly resistant to the influence of sulfanilamide was not determined experimentally.

Effect of Sulfanilamide on Staphylococci.—While sulfanilamide appears to be capable of sterilizing human urine containing staphylococci, it is of doubtful therapeutic value in the treatment of bacteremia and in conditions in which the deeper tissues have been invaded by the organisms, according to Spink. This discrepancy in therapeutic effectiveness prompted him to study the bactericidal effect in vitro of sulfanilamide on various strains of staphylococci. The influence of each of the following factors on this bactericidal effect has been observed: the culture mediums, with special reference to their ingredients; the strain of staphylococcus; the number of organisms in the original inoculation; the concentration of sulfanilamide; the temperature at which the suspensions of organisms and the drug were incubated, and the initial pH of the substrate. Nineteen strains of staphylococci have been included in this study. Twelve strains belonged to the pathogenic group, and seven were considered nonpathogenic. Sulfanilamide in high concentrations had little or no bactericidal effect on organisms suspended in peptone broth and incubated at 37 C. When the mixtures of organisms and the drug were incubated at 40 C., the bactericidal effect was more pronounced. Sulfanilamide was bactericidal for the strains when the organisms were suspended in urine. The maximum effect took place at an incubation of 40 C. and was not dependent on the initial pH of the urine. The presence of small quantities of added peptone in urine completely interfered with the bactericidal action of the drug. Discussing the

significance of this action of peptone the author points out that, although peptone appears to interfere with the action of sulfanilamide on the hemolytic streptococcus, this interference seems more marked for the staphylococcus. This may account in part for the failure of sulfanilamide in the treatment of staphylococcal sepsis. The author has treated persons with sulfanilamide whose tissues were invaded by both beta hemolytic streptococcus and Staphylococcus aureus. After a period of therapy, bacteriologic studies of material from the invaded areas revealed the absence of the streptococcus, but staphylococci were still present. He suggests that in staphylococcal sepsis in which tissue necrosis is a feature of this type of sepsis, peptone-like substances are formed as the result of the breakdown of protein material and this interferes with the action of sulfanilamide on the organisms. He shows that recent studies by several investigators (Lockwood, Larson, Shaffer), although not fully explaining the relationship of peptone to the activity of sulfanilamide, throw some light on this important problem.

Fever Therapy and Carbohydrate Metabolism.—Kirstein and Bromberg declare that hyperglycemia during fever therapy is not due to blood concentration but to disturbances in carbohydrate metabolism. This concept may have an important bearing on the preparation of patients for hyperpyrexia, especially diabetic persons. One of the important pathologic factors in diabetes is the tendency toward an increased rate of glycogenolysis in the liver. If any factor which stimulates glycogenolysis (such as artificial fever) is superimposed on this, the result may be excessive hyperglycemia, glycosuria and frequently ketosis. (This may also explain the response of persons with diabetes to infectious fevers.) The vicious process can be combated by means of adequate administration of carbohydrates and by inhibiting the rate of glycogenolysis with insulin.

Iron in Skin in Hemochromatosis.—Fishback outlines a simple test for demonstrating cutaneous iron in hemochromatosis. He mixes equal parts of sterile solutions of 0.5 per cent potassium ferrocyanide and hundredth normal hydrochloric acid and injects the resultant solution intradermally so as to form a wheal. A slight blueness is evident almost immediately, which darkens to a deep blue within five minutes. A narrow red zone appears at the periphery of the wheal in about two days. This persists throughout the slow contraction of the blue test spot until it disappears in about two weeks. The negative test shows a white wheal in which the peripheral red zone develops later and disappears in about the same time as a positive test. There is a sharp stinging sensation with the injection, but it ceases within a few seconds. There is no pain or itching afterward. The skin remains intact without peeling or necrosis. Since diffuse iron deposit occurs only in hemochromatosis, this test would appear to be specific for the disease. In hemochromatosis the test is also positive after death.

Dementia Praecox and Insulin.—The condition of 1,039 patients with dementia praecox who received insulin shocks prior to March 1938 is given by Malzberg, who asserts that 134 were reported as recovered after the completion of treatment, 282 were much improved and 263 improved. This makes a total of 679, or 65.4 per cent, who showed some degree of improvement following treatment with insulin. Compared with a corresponding group of patients who received no specific shock therapy, the results obtained were remarkably favorable. Thirteen patients died during the course of treatment. After much shifting in the results of the 134 patients described as recovered at the termination of treatment, only seventy-three were so described at the time of the follow-up (14.4 months after completion of treatment). Of the remainder, twenty-one were much improved, seventeen improved and twenty unimproved. Of the 282 much improved patients, 111 remained in this category; however, forty-three improved to such a degree that they were considered as being recovered. On the other hand, 162 had deteriorated and fifty-five were described as merely improved and sixty-seven as unimproved. Of the 263 who had originally been considered as improved, 116 had deteriorated during the ensuing year. But thirty-eight showed further improvement, eleven of whom were considered recovered. Finally, of the 347 originally deemed as unimproved, five later showed a complete recovery, eleven were much improved and twenty-one were improved. Though some patients showed various degrees of deterioration in their mental status following the termination of insulin therapy, an appreciable total continued to improve, a phenomenon that was observed also by Sakel, who likened it to a process of ripening. Approximately an average of fourteen months after the termination of insulin therapy, 12.9 per cent of the patients were described as recovered and 49 per cent as improved to some degree. There was thus a significant reduction in the percentage of

patients who maintained their improved status. Nevertheless the author declares that this percentage is in significant excess of corresponding results among similar patients who did not receive specific shock therapy. Paranoid and catatonic types of patients showed better results than hebephrenic individuals. Patients with a short duration of the disease prior to treatment showed the highest rates of recovery and improvement. Those regarded as recovered and much improved showed the highest rates of discharge and parole and the lowest rates of relapse. Therefore it is evident that to secure the best results it is necessary to institute treatment in the early periods of the disease.

Gas Bacillus Infection of Abdominal Wall.—Clute and Anglem report two cases of gas bacillus infection of the abdominal wall complicating cecostomy done for obstructing carcinoma of the colon. Both patients recovered after treatment with polyvalent gas bacillus antitoxin. In the first case the simultaneous occurrence of a constricting annular carcinoma of the splenic flexure and a volvulus of the sigmoid were the most significant feature. It constituted virtually a closed intestinal loop, which has been shown to provide optimal conditions for the proliferation of *Clostridium welchii*. The diagnosis in the fulminating type of infection represented by this case is usually made without difficulty. The process develops with lightning-like rapidity and usually occurs within twenty-four to thirty-six hours after operation. The pulse and temperature rise abruptly and the patient is in a state of severe shock which appears out of proportion to the local observations. There is generally delirium and there is severe pain referred to the wound. The local observations, the coppery red discoloration of the skin, the crepitation and the marked tenderness on palpation are classic. The second patient, who had a carcinoma of the transverse colon, underwent a purse-string type of cecostomy. The patient's convalescence was entirely without incident until the seventh postoperative day, when the temperature rose to 102 F. and the pulse to 115. On the following morning the discoloration had taken on the coppery red color characteristic of *Clostridium welchii* infection. Crepitus, which could be heard with a stethoscope, was present in the tissues all about the incision. The report on the culture was somewhat equivocal. Nevertheless the clinical features of the disease, while not so fulminant as in the first

case, were so clearcut and definite that the authors had no doubt whatever that it represented a gas bacillus infection of the abdominal wall. The successful treatment of gas bacillus infection is dependent on early recognition and immediate institution of therapeutic measures. The rarity of this type of infection as a complication of abdominal surgery may lead to confusion and failure to establish the diagnosis. Delay may be fatal. If there is suspicion of gas bacillus infection, smears and cultures should be made at once. While waiting for culture reports, however, active treatment should be instituted at once of any patient who is suspected of having gas bacillus infection. The wound must be widely and freely opened by removing the skin and fascial sutures. In each of the reported cases only the peritoneal suture line was left intact after the wounds were opened. Dressings wet with hydrogen peroxide may be applied to the wounds and should be kept saturated with this solution. The authors relied almost entirely on the use of large amounts of polyvalent gas bacillus antitoxin with excellent results. In early 1937 sulfanilamide had not been proved beneficial in gas bacillus infection and it was not used. Today it would be used but the authors think that the antitoxin should be used as well. In the fulminating type of infection they administer daily by intravenous injection from three to four ampules (from 90 to 120 cc.) of antitoxin. This is continued until the infection is under control. It may be necessary to continue treatment for seven days or longer. In the milder cases the dosage of antitoxin may be from two to three ampules (60 to 90 cc.) daily.

Sulfapyridine for Pneumonia.—Rawlings and Hamilton report the results obtained in six cases of bronchial and twenty-four cases of lobar pneumonia following treatment with sulfapyridine. There were two deaths; in both, tuberculosis was a complication. Other aids in addition to sulfapyridine were used when it was felt that they would be of value. In addition to the drug, oxygen was given to seventeen patients, transfusions to seven and serum to four. Four fifths of the patients had complications of varying grades. The average dose of sulfapyridine was 39.19 Gm., but for the mild cases showing minimal complications it was 22.11 Gm. Leukocyte counts were extremely helpful in following the condition of the patients, and when there was any indication that the counts were low and the patient's condition not otherwise good, transfusions and serum were used. One danger resulting from the use of the drug, in addition to the gastric disturbance, is seemingly an evident depression of the formation of erythrocytes or their destruction. By blood culture or sputum typing, twenty-eight of the thirty cases of pneumococcic pneumonia were proved. Of these proved cases recovery occurred in all but one, giving a final mortality of but 3.93 per cent of the proved cases. The authors state that the only untoward result in their cases was the presence of a definite anemia in seven. They conclude that patients with lobar or bronchial pneumonia whose prognosis has heretofore been considered completely hopeless by older methods of treatment can, by the combined use of their six measures, have a much greater likelihood of living. These measures consist of early use of sulfapyridine, oxygen when the temperature is 101.5 F. or more, a pulse of more than 120 and respirations over twenty-four per minute, adequate use of dextrose and saline solution when indicated, digitalization of all heart failures, serum in large amounts in all critical cases, and adequate use of transfusions when anemia is present. Two other general procedures that should not be neglected are the use of liver extract in cases of leukopenia and ascorbic acid, thiamin chloride, riboflavin and small amounts of nicotinic acid in many of the borderline avitaminoses or when general bodily metabolism is not optimal.

Familial Primary Glaucoma in Adults.—Briggs has encountered two families in which simple glaucoma appears to be a familial condition. The mechanism by which the hereditary influence acts is unknown; defective development of the angle of the anterior chamber seems to be the most probable cause, but statistics suggest that the causes of buphthalmia, hereditary glaucoma and nonhereditary glaucoma are separate and distinct. There seems to be no association between hereditary primary glaucoma and buphthalmia. There is little evidence to support the suggestion that hereditary glaucoma is due to some degree of congenital microphthalmia with a disproportionately large lens. The first family that the author describes was probably affected through three generations, but no cases have yet been discovered in the fourth, although, curiously enough, several members of the fourth generation have defective sight. The three patients of the fourth generation who have come under observation have been found to be suffering from quite unrelated disorders of the eyes and to show no sign of glaucoma. Of eleven legitimate children of the third generation, two died in infancy; of the remaining nine, three were certainly glaucomatous and two more suffered from optic defects which were probably glaucoma; two more had defective sight which may have been due to glaucoma, and two were unaffected. One of the two unaffected members died at the age of 24, too early for the condition to be ascertained. In one member of this family a spontaneous choroidal detachment developed about three months after sclerocorneal trephining, and this persisted unchanged for a year. It was (unsuccessfully) treated by a cautery puncture and is still present. The second family comprises ten siblings, one of whom died in infancy. Of the nine living siblings, eight are said to be glaucomatous and six have been examined. Of these, five were glaucomatous and one was unaffected.

Poliomyelitis and Intellectual Capacity.—Gordon and his colleagues determined the intelligence quotients, by the Stanford-Binet scale, of ninety-eight children from 4 to 16 years of age under treatment for acute anterior poliomyelitis or its residual effects. In some of these children the onset of the disease occurred several years before the tests were applied. The mean intelligence quotient of the group was 103.91, with a standard deviation of 15.89. In comparison with a random group of normal school children whose mean intelligence quotient was 98.8 and standard deviation 15.2 it is seen that the mean performance of children who are suffering or have suffered from poliomyelitis does not fall below the performance of a random group of normal children drawn from the general population. A more precise examination showed that the distribution of intelligence quotients did not show any significant departure from what would be expected on the basis of the normal curve. The result was what would be obtained from a sample of similar size drawn from the general population. Therefore it can be concluded that children who suffer from poliomyelitis give just the same average results as do ordinary normal children and

that the variability of the results also (their spread and range) is that of a normal group. The mean intelligence quotient of the forty-six girls was 102.1 and of the fifty-two boys 105.5. The difference is not statistically significant. Neither was there any association between the intelligence quotient and the age of onset of the disease, the interval between onset of the disease and the performance of the test or the occurrence of clinically recognizable cerebral symptoms at the onset of the disease.

Poliomyelitis and Chronic Lethargic Encephalitis.—In examining microscopic films of the cord, brain, lymph glands, spleen and other organs of human beings and monkeys with acute poliomyelitis, Coles found certain microscopic structures which are not normally present. Small sporelike organisms staining blue with Giemsa stain and varying in size from almost invisible bodies to those from 3 to 5 microns or more in diameter were found in the cord, brain, lymph glands and heart blood of infected monkeys and in the cord and brain of human subjects. Many of the larger forms have more deeply stained spots in their interior as if they were undergoing development. Somewhat similar blue-stained spores were found in films from the nasopharynx. The same bodies were present in many of the capillaries of the cord and brain of human and animal subjects. Cystlike bodies, staining red with Giemsa stain, measured on an average from 3 to 6 microns and showed evidence of some internal structure. Intracellular Negri-like bodies measuring from 1 to 14 microns were found in the cord and brain of human beings and monkeys. Films of the cord and brain of two subjects with acute poliomyelitis showed all the forms seen in acute poliomyelitis, but in comparatively smaller numbers. In preparations from the brain of a subject with chronic lethargic encephalitis, all these structures were present and the blue-stained sporelike bodies, both free and intracapillary, were numerous. These films were practically indistinguishable, from a morphologic point of view, from those of poliomyelitis. In films of the infective filtrates of the cord suspension of three monkeys with poliomyelitis, extremely small, round or oval, well defined elementary bodies measuring from 0.15 to 0.2 or 0.3 micron were present. These stained a reddish color and occurred in almost pure cultures. It seems highly probable to the author that these elementary bodies are the actual causal virus of poliomyelitis. It is possible that the sporelike, cystlike and intracellular bodies are stages in the development of an organism which in its final stage is a filtrable body.

Testosterone Propionate in Chronic Mastitis.—Spence reports observations on twenty-four patients with painful breasts and so-called chronic mastitis. In view of the pronounced psychologic element in the genesis of mammary pain, all patients were first treated with intramuscular injections of sterile olive oil as a placebo twice a week for several weeks. Thirteen patients had a dramatic improvement in the pain, whether it was continuous or not. Four patients thus improved had a fairly large lump in the breast. A large nodular mass in the right breast of one patient disappeared during the control period of three months. Had she been receiving testosterone, the improvement in the breast would have been ascribed to this. To eight patients with no lumps whose pain was completely or greatly relieved with olive oil, no further treatment was given. To sixteen patients whose breasts contained a lump or whose pain was not relieved

by olive oil, intramuscular injections of testosterone propionate were given twice or three times a week. The dose employed for most patients at first was 25 mg. twice a week. If the response to this after a few weeks was unsatisfactory, the dose was increased to 50 mg. twice a week and later for some to 100 mg. twice or three times a week. Treatment was continued for various periods, depending on the response. There was thus a considerable variation in the total dosage, some patients receiving only from 100 to 500 mg. and others as much as from 2,000 to nearly 3,000 mg. Fourteen of the sixteen patients had relief from pain. Twelve patients treated had lumps in the breast; the lumps of three disappeared, but for two of these spontaneous disappearance could not be excluded, and for one 2,925 mg. in five months was required, resulting in hypertrophy of the clitoris and extreme atrophy of the endometrium. Five patients had some reduction in the size of the nodules. Of two who were not improved, fresh nodules appeared in the breast during treatment. Menstruation of seven patients receiving the larger doses was suppressed. Five of the younger patients had and increased growth of hair, four with comparatively small doses, but this was not observed in older patients receiving much larger doses. It is emphasized that because of this complication and the undesirability of prolonged atrophy of the endometrium, testosterone propionate should be used with caution for women.

Prolactin for Nursing Women.—In the experiments described by Kenny and King two preparations of prolactin, one from ox pituitary and the other from sheep, were administered to forty-three women during the period of lactation. The women were selected as deficient in milk secretion at different stages of this period up to the third month. In three cases milk secretion was absent until administration of prolactin was begun on the ninth or tenth day after delivery. All cases were followed up for at least three months and most for six or seven months. The response to administration was classified as positive, partial or negative. A positive response indicated that the increase in milk secretion was maintained at over 3 ounces (100 cc.) a day. A partial response indicated an increased yield of from 1½ to 3 ounces (50 to 100 cc.) of milk a day, or a larger yield which was not maintained when the injections of prolactin were stopped. An increase of less than 1½ ounces (50 cc.) was classified as a negative response, a failure. Prolactin was given in the early stages of the period of lactation, when clinical experience or the past history indicated that the patient would probably not have sufficient milk. In the later weeks deficiency or decrease in lactation was treated. At present it is the practice of the authors to begin treatment as early as possible, so that efficient nursing may be established before discharge from the hospital. They employed a total dosage of 15 cc. (900 Riddle units) of prolactin in each case, spread over five days, thus: first and second days 5 cc. daily, third and fourth days 2 cc. daily, and fifth day 1 cc. The quantity was given by the intramuscular route into the buttock or arm. To a few neurotic women an injection of sterile saline solution 2 cc. was given forty-eight hours before the start of treatment with prolactin. This suggestion therapy did not evoke a response in any case. In the dosage described, the extracts appear to have no systemic or local ill effect. Dextrose tolerance tests have not shown any departures from those of control lactating women. Depression of the gonadotropic function has not been observed. The quality of the milk secreted after administration of the extracts is essentially the same as that of control samples. About the effect on the lactation, the authors say that in three fourths of the women with deficient lactation in the first eight weeks of the lactation period satisfactory nursing was induced with prolactin. A further few cases showed only a temporary or moderate increase of milk secretion after the administration of prolactin and in 19 per cent there was either a small increase or none at all.

*Therapies Employed in Hemogenia: Value of Roentgen Therapy. M. Lévy and L. Gally.—p. 1420.

Roentgen Therapy of Spleen in Hemogenia.—Lévy and Gally appraise the therapeutic managements at present employed in hemogenia, such as splenectomy and various treatments of a nonsurgical character. They select four of their twenty-eight cases, in which roentgen treatment was successfully instituted, for special discussion. The four women with age level between 26 and 49 manifested a hemorrhagic diathesis in epistaxis and menorrhagias, accompanied with ecchymosis in one case. The bleeding time indicated was between four and one half and forty-five minutes, the clotting time between eighteen and twenty-six minutes. The treatments varied from a total of 870 roentgens to a total of 4,500. The curative results achieved included hemostasis at the nose, gums and skin, reduction of the bleeding time from eight to one and one half minutes in one case and clotting time from eighteen minutes to six minutes in another and normalization of the menstrual flow in one case after the first application of 250 roentgens. One patient, examined after two years, had had a normal pregnancy and delivery. The authors think that the negative results reported by others for roentgen therapy are due to several factors: (1) insufficient dosage (in one case a total of 200 roentgens was reported), (2) inattention to individual sensitivity variations (in one case a cure may be effected by 250 roentgens whereas another may require 1,500 and more) and (3) failure to recognize that the whole reticulo-endothelial system may be involved, not merely the spleen. The authors consider their clinical results satisfactory. In their most serious case hemostasis persisted after five years. The erythrocytic counts became normal without antianemic medication. They reject splenectomy in benign and acute cases because of the high immediate or delayed mortality and the recidivations due to surgery, some brilliant operative achievements notwithstanding. They recommend the application of roentgen therapy not only to the spleen but to the whole reticulo-endothelial system, especially the areas rich in ganglions, such as the inguinal and axillary, since hyperfunction of the spleen may be secondary to hyperfunction of the reticulo-endothelial system. The systematic use of roentgen therapy in benign cases may constitute a prophylaxis against further evolution and make operation unnecessary.

Reasons for Employment of Electromagnetic Waves in Gastro-Enterologic Surgery. H. Paschoud.—p. 226.

Hyperazotemia in Digestive Hemorrhages.—Demole and Neeser say that it was Sanguinetti who in 1933 first called attention to the appearance of uremia following gastrointestinal hemorrhages. In view of the fact that the increase in the urea content of the blood is slight after intestinal hemorrhages, the authors prefer the term "hyperazotemia" to uremia. They investigated this condition in a series of fifty cases. They found that digestive hemorrhages provoke an elevation in the urea content of the blood in three of four cases. This hyperazotemia is mild; it appears early and is not lasting. It is accompanied by a strong augmentation of the urinary secretion of urea and by hypochloruria, whereas the chlorides of the blood vary hardly at all. It does not seem to have an unfavorable clinical significance. It does not indicate an unfavorable prognosis. It has no direct relationship to the abundance of the loss of blood, the degree of anemia or the nature of the causal lesion. Among the factors that have been invoked to explain the hyperazotemia that follows digestive hemorrhages, chloropenia can be excluded. The tissular disintegration consecutive to fasting for one part and purely functional renal disturbances for another

part assume an occasional or a supporting role but are always secondary. The resorption of the blood poured into the intestine is certainly the chief cause of the hyperazotemia. The authors show that the arguments in opposition to this theory are refuted by clinical and experimental evidence. In hematemesis, when nearly all the blood is expelled through the mouth, the urea content of the blood is rarely elevated; however, in melena, when the blood remains for some time in the intestine, hyperazotemia develops in five of six cases.

Treatment of Pneumonia and Bronchopneumonia by 2-(Para-Amino-phenylsulfamide) Pyridine. I. Cugnini.—p. 387.

Pyelography in Extrarenal Abdominal Tumors.—Guardabassi discusses the value of pyelography in the diagnosis of extrarenal abdominal tumors in twenty-seven cases. Outward lateral displacements of the kidney are caused by paravertebral tumors (abscess, aneurysm of the aorta and tumors of the lumbotracheal lymph nodes) as well as by tumors of the adrenal capsule. Medial displacements of the structure are rare. Only one case was observed in the group of cases reported. It was a case of metastasis of the renal region from cancer of the uterus. Downward displacements of the kidney are caused by tumors which are located in structures near the upper zone of the renal cavity, namely adrenal tumors or echinococcal cysts, retroperitoneal or at the root of the mesentery. They may also be caused by tumors of the spleen and the liver, if acute splenomegaly or hepatomegaly exists. Upward displacements of the kidney are rare. They may be caused by certain retroperitoneal tumors. Backward displacements are caused by large abdominal tumors (paravertebral cystofibrosarcoma, dermoid cysts of the ovary and large tumors of the liver). Outward frontal displacement is rare. No case of the type was seen in the group reported by the author. The ureters may be displaced by retroperitoneal tumors only, which are those displacing either the structure or the kidney more frequently than any other extrarenal abdominal tumor. Intraperitoneal tumors compress the ureters without displacing them. Displacement of the pelvis is rare. It was observed in only one case of twelve cases of intraperitoneal abdominal tumors in the group of cases reported by the author. It was a case of retroperitoneal metastases from a large ovarian cystosarcoma. The most frequent morphologic alteration of the urinary tract from extrarenal abdominal tumors is a more or less acute dilatation of the pelvis and ureters from tumoral compression or else by propagation of the tumor or by metastases.

- *Pathogenesis of Infantile Tetany. A. Dordi.—p. 527.
Medical Treatment of Acute Anterior Poliomyelitis. P. Tolentino.—p. 536.

Infantile Tetany.—Dordi discusses the pathogenesis of infantile tetany, with especial reference to the role of increased guanidinemia. Because of the fact that infantile tetany is often associated with spasmophilia, the author followed the behavior of guanidine in the blood of nine infants who were suffering from infantile tetany with or without rickets but uncomplicated by any other disease. He also followed the behavior of the electrolytes in the blood. The diagnosis of spasmophilia in the cases reported by the author was made by (1) the clinical symptoms, (2) the results of the electrical stimulation of the median nerve and (3) the verification of the presence of hypocalcemia. The author found that when the determinations of the substances in the blood were made during actual tetany the amount of guanidine in the blood was normal, that of calcium was diminished and that of potassium was moderately increased. When the determinations were made after recovery of the patients, the amount of guanidine in the blood had remained unchanged, whereas those of calcium and potassium had returned to normal. The author believes that an increased amount of guanidine in the blood in the course of certain diseases in chil-

dren may be the cause of tetanoid symptoms complicating the disease. However, it is not the pathogenic agent of infantile tetany which is caused by a rupture of the equilibrium of the electrolytes in the blood (hypocalcemia in infantile tetany and hyperpotassemia in experimental guanidine tetany).

Movements of Diaphragm and Thorax After Deepest Inspiration and Expiration. A. J. Anthony and M. Broglie.—p. 627.

Hereditary Fibrinopenia.—Schönholzer's patient, a boy of clinically healthy parents, was first hospitalized for serious epistaxis when about 12 years of age. He was rehospitalized twice during a period extending over more than three and one-half years and finally died of a severe pulmonary edema. Anamnesis disclosed umbilical hemorrhage at birth lasting twelve days, a fall when 2 years old that injured his head and caused an enormous subcutaneous hematoma and since then a persistent tendency to bleeding, especially at the gums on tooth extraction. At his first hospitalization, tamponage and a blood transfusion of 600 cc. were immediately effective and his recovery from serious anemia, as the result of appropriate medication, rapid. He was rehospitalized one and one-half years after for pronounced anemia and severe pain in the left side of the thorax and in the stomach. A large blood effusion in the left pleura was discovered. A blood transfusion of 350 cc. was at once made. A subsequent pleural puncture showed almost pure sterile blood. Treatments for anemia were resumed and made possible his discharge. Several months later a special hematologic analysis was undertaken. No trace of fibrin formation was discoverable even after forty-eight hours and neither blood nor plasma would clot in the test tube. The patient was hospitalized for the third time about two years subsequently. Increasing fatigue, pallor, slight nasal and pharyngeal hemorrhages and a comatose condition were noted. The analysis of the blood albumin indicated the complete absence of fibrinogen in spite of various tests. Blood clotting was attained only on heating at 165.2 F. Sternal puncture performed immediately after the patient's death revealed a large decrease of plasma cells and a large increase of reticular cells. Necropsy showed a clinical picture of extensive intracranial bleedings and a huge epidural hematoma. Among the thirty-nine family members traced by the author, the following familial facts are brought out: A sister of the patient died seventeen days after birth from uncontrollable umbilical hemorrhage; another sister aged 15, while clinically healthy, was found to have a blood clotting time of twenty-one minutes and a fibrinogen level of 0.13; a maternal grandfather had a lifelong hemorrhagic diathesis, especially of the gums, and, like his sister, died of apoplexy. The other blood relatives examined were normal; for those who could not be examined a normal anamnesis was reported. In his discussion of hereditary fibrinopenia, the author distinguishes between fibrinogen deficiency (fibrinopenia) and fibrinogen absence (afibrinemia), the latter represented by this case. The former disease is compatible with a normal life. Predisposition to bleeding is slight and clotting time nearly or altogether normal. A congenital tendency to fibrinopenia, however, is recognizable on further examination as hereditary. The second disease, an exacerbation of the former, invariably occurs in children and its prognosis is unfavorable. The disease is characterized by a complete absence of fibrinogens in the plasma and the consequent incoagulability of the blood. Etiologically the author considers the bone marrow chiefly, though not exclusively, implicated. The significance of plasma cell involvement needs, he says, further investigation. Activation of congenital hemorrhagic diathesis is attributable chiefly to traumas that need only be slight. However, multiple bleedings suggest the implication of the vascular system, perhaps under the influence of intercurrent infections. The author thinks that the facts point to a recessive heredity of an intermediate kind that is not sex limited.

*Protective Inoculations Against Diphtheria and Schick Test. Thea Steinhardt.—p. 843.

Diphtheria Inoculations and the Schick Test.—Steinhardt reports the results of several years' experiments with protective inoculations against diphtheria and the reliability of the Schick test. The experiments were carried out in several series. Of 151 Schick positive children injected with 1 cc. of alum toxoid, seventy (46 per cent) became Schick negative, fifty-five in from two to five and fifteen in from six to eight weeks. During this period, eighty-one (54 per cent) remained Schick positive. Reexamination by the Jensen method of forty-six of the seventy Schick negative children from eight to ten months later disclosed that 80 per cent had an antitoxin titer of over 0.01 and 20 per cent a titer under this figure. Simultaneous examination of the eighty-one children remaining Schick positive disclosed that 47 per cent became Schick negative without having diphtheria or becoming immunized in the meantime. In another series of experiments, sixty-eight Schick positive children with titer under 0.0005 were injected with 1 cc. of alum toxoid. Eighty-three per cent showed increase over this figure in from four to five weeks, but only 67 per cent showed increase over the figure of 0.01. Examination of twenty-one of the sixty-eight children from eight to ten months later disclosed that only two of the children had a decreased titer to under 0.01 and in eleven children there was a further increase of titer. Children with titers over 0.0005 displayed enormous increase of titer following the injection. The antitoxin titer of twenty-eight of these children was again examined from one and a half to two years later, this time according to the intracutaneous method of Römer on guinea pigs, and in only fourteen cases (50 per cent) was the Schick standard set at 0.01 attained. In all, 301 Schick reactions were carried out and the percentage of error was about 7 per cent. Schick tests with decreased doses of toxin gave no practicable results. The author is in favor of immunization and recommends it at the age of from 10 to 11 months at the time of vaccination against smallpox. He likewise recommends a second injection from eight to ten months after the first.

Sulfanilamide for Chancroid and Accompanying Buboec.—Kristjansen says that after one series of treatments (13.5 Gm. of sulfanilamide) nine of twelve cases of chancroid were cured in from eight to ten days and there was no recurrence; two of the cases were complicated with buboec. The infection at the start of treatment was from seventeen to 105 days old. In one instance a second series of treatments after an interval of two weeks was effective; the complicating bubo was healed during the first series. In one case, with infection five months old, supplementary treatment with iodoform was necessary, and in one case, with infection three weeks old, complicated with a large bubo resistant to sulfanilamide four injections of dmecos vaccine resulted in healing without perforation. The by-effects of the treatment were slight; in two cases there were nausea and headache which did not necessitate interruption of the treatment. The average length of hospitalization was 20.3 days, as against an average of 35.3 days for the twelve patients with chancroid treated immediately before the introduction of streptomycin.

How to Elicit and Evaluate the Patient's Complaint

GILES A. KOELSCH, M.D.
ROCHESTER, MINN.

My purpose in this discussion is to help the physician, especially the recently graduated one, to acquire effective methods of attacking a clinical problem and, by specific and concrete suggestions concerning the art and science of history taking, to enable him to acquire this ability more quickly than he might otherwise acquire it.

The medical student is introduced to the subject of history taking by memorizing a list of questions which he will put to his patients. These questions have to do with all the symptoms which may manifest themselves in all parts of the human body during a lifetime. Early in his medical practice, however, he learns that the patient's answers to these questions do not necessarily constitute an accurate or diagnostically helpful clinical history.

OBJECTIVES

In eliciting a clinical history there are three main objectives which a physician should strive to attain: First, from the data that the patient gives he must be able to cull the significant facts which, when developed into a history, may lead to a correct diagnosis. In order to be able to do this he must know well the symptoms of all the diseases to which mankind is subject. The man who is an expert at detecting counterfeit money acquires this ability by becoming thoroughly familiar with all characteristics of the genuine. So the man who is to evaluate properly a patient's complaints must be familiar with those symptoms which indicate organic disease so that he may be able to recognize those which do not.

Second, he must strive to develop speed in taking histories. In the practice of medicine as in any other profession, while accuracy in observation and judgment is absolutely essential the element of conservation of time also is of great practical importance. This is especially obvious in group practice, in which the slowness of one physician increases the load which the

other members of the group must sustain. Speed must not be attained at the expense of accuracy, but with practice both can be achieved.

Third, he must strive to please each patient. Patients vary greatly as to their emotional stability, intellectual capacity, keenness of perception and general reaction to the questioning and examination which enable the physician to make a diagnosis. One patient may respond intelligently to, while another patient may be affronted by, the same question put to the two patients in the same courteous way. Therefore the physician must develop an extreme amount of mental flexibility so that he may be able not only to discern quickly the type of personality with which he has to deal but also to put his questions in a way best suited to that personality.

Having considered the three main objectives to be achieved in eliciting a clinical history, let us consider methods by which their attainment is made possible. The assault on any clinical problem can be carried out advantageously in three stages, preferably in the following order: first, eliciting the patient's major complaint and all data pertinent thereto, jotting down notes concerning the significant facts; second, examining the patient while inquiring concerning symptoms referable to all parts of the body other than those discussed in the major complaint; third, composing the clinical history and recording it together with physical observations. These stages will be discussed in the order noted.

FOUR IMPORTANT QUESTIONS

The manner of the physician's approach to patients is of great importance. His attitude should be kindly, disarming, gentle, sympathetic, unhurried, self confident but not arrogant, and free from any trace of brusqueness. He should not make a mental diagnosis of their ailments immediately on meeting them, for they are quick to sense and resent a physician's preconceived ideas about their

symptoms. The physician's approach may inspire patients with confidence and put them completely at ease, or it may arouse a combative spirit which may result in a mental barrier between them and himself that cannot easily be broken down. Kilgore¹ summarized the problem well when he stated that the physician's approach should be intellectual rather than mechanical.

THE FIRST QUESTION

Physicians have various ways of putting their first question to patients. Introductory inquiries commonly employed are "Why do you come to me for an examination?" "What bothers you?" In my experience these questions not infrequently result in one of the following replies: "To find out what's wrong with me"; "That's what I came to you to find out," or "That's what I'd like to know." I prefer an initial question which gives patients no option in replying but to give the information desired. My favorite is "In what way have you been suffering that made you decide to seek medical counsel?" The question "Of what do you complain?" also may persuade the patient to relate significant symptoms. Next, one should ascertain the duration of the major complaint. If it is of considerable duration, an important follow-up question is "What made you decide to come just now?" This often yields most useful information so far as getting the proper perspective of the problem as a whole is concerned. For example, a patient gives pain in the precordial area of two years' duration as a major complaint, but the factor that crystallized his decision to come for an examination when he did come was that his family physician had recommended it because of his diagnosis of angina pectoris. Another patient gives as his major complaint attacks of epigastric pain of fifteen years' duration which are characteristic of the pain of duodenal ulcer, but the factor that crystallized his decision to go to the physician when he did go was a gastrointestinal hemorrhage four weeks previously. Another patient comes when he did because his symptoms had been getting progressively worse, another simply because it was a convenient time to get away from his work and not because of any recent change in symptomatology. Yet another patient gives constant pain in the lower part of the back following a blow in that region five years previously as a major complaint, but the threat of discontinuance of compensation may have crystallized his decision to come, although he won't give this information without tactful questioning.

Another fact which should be established early in the process of eliciting a clinical history in order that the symptoms may be evaluated

properly is whether or not there has been any disability. A patient may complain bitterly of pain, yet when asked if it keeps him from work he may admit that he does work in spite of it. The question that I prefer is "How long have you been unable to carry on your usual activities because of your pain?" or because of whatever symptom it may be of which the patient chiefly complains.

Having established the patient's main complaint and its approximate duration, the factor that made him decide to seek medical counsel when he did seek it, and the presence or absence of disability, one should encourage the patient to describe his symptoms in detail in his own words. The factual data gathered thereby may or may not be of great value but the manner in which the patient relates his symptoms can be, and often is, of considerable diagnostic importance in separating functional from organic disease.

Ward² has stated that the greater the number of symptoms of which the patient complains and the more complete the details with which they are described and presented, the more likely is their origin to be neurotic. Stated in another way, the longer the clinical history, the greater the probability that the symptoms are of functional origin.

When patients describe their symptoms with hyperbolic adjectives, the importance and significance of symptoms so described are greatly lessened. Ward points out that the patient with an agonizing headache one day may have an excruciating abdominal pain one week later and in another week may have a terrible pain in the foot. It should be emphasized that patients with organic disease usually present their symptoms in a simple manner unembellished with superlative adjectives.

It is common knowledge that the patient who brings several sheets of paper on which he has recorded all his symptoms so that he will be sure not to forget any of them almost certainly is suffering from functional disease.

CHRONOLOGY

In order for a history to have diagnostic value, the symptoms must be detailed in chronologic order. This is of equal importance whether the symptoms are due to functional or to organic disease. Polak³ stated that sequence of symptoms makes diagnosis. J. B. Murphy⁴ wrote that, in 2,000 cases of appendicitis, sequence of symptoms gave positive diagnosis in 1,998. For example, a woman 24 years of age presented as a major complaint jaundice of two years' duration. Inquiry as to sequence of events

1. Kilgore, E. S.: *Clinical Records: A Criticism of the Present Vogue*, J. A. M. A. 97: 93-95 (July 11) 1931.

2. Ward, Ernest: *Clinical Histories*, Clin. J. 65: 338-345 (Aug) 1936.

3. Quoted by Nix, J. T.: *How Can Scientific Clinical Records Be Assured?* Bull. Am. Coll. Surgeons 16: 19-22 (June) 1932.

disclosed the following facts: Beginning two and a half years before, and recurring on the average of two to three times a month, the patient had had typical attacks of gallstone colic. After enduring these spells for six months, the patient submitted to cholecystectomy. There had been no jaundice before the operation. Three weeks postoperatively, when the T tube was removed, jaundice associated with chills and fever gradually developed. The chills and fever continued for only one to two weeks but the patient remained intensely jaundiced, passing bile stained urine and acholic stools. Six weeks previous to her present examination, profuse epistaxis had occurred, following which she was given a blood transfusion. The order in which her symptoms developed suggested that her jaundice was of the obstructive type, most likely secondary to a stricture of the common bile duct. This diagnosis was confirmed when exploratory operation was performed.

QUESTIONS ABOUT PREVIOUS EVENTS

If the symptoms are due to functional disease, the physician should inquire carefully into the events leading up to their development. For example, a woman may develop weakness of one arm after eighteen months of caring for an invalid mother who is suffering from a stroke. A man may develop symptoms of functional indigestion after reporting to his business associate's apartment for Sunday morning breakfast and discovering that his partner has just shot himself. Another man may complain of trouble using his right arm after filling out complicated sales-order sheets for fifteen years without having had a vacation during that time.

With such problems it is a simple matter to describe the patient's symptoms, and the physician taking the history may even suspect that the symptoms are functional; but to find out the facts recorded above, which antedate the development of the symptoms themselves and are directly related to them etiologically, requires much tact and mental ingenuity. One must have a low threshold of suspicion for functional disease and, if there are features about the symptoms that are not typical of organic disease, one must attempt to find out the factors likely to be responsible for the symptoms.

Kilgore has described a case that emphasizes this point in a striking way. The patient was a woman 45 years of age who always had enjoyed the best of health until the death of her husband one year previously. She looked hopefully to her eldest son for support, but nine months after her husband's death she gradually experienced the final and crushing conviction that the son's talents were limited to selling newspapers at a

profit of less than a dollar a day. Therefore, in addition to caring for her home and her three other children, she took employment in a restaurant, where she stood eight hours daily washing dishes. Then came backache, sleepless nights of worry, anorexia, loss of 20 pounds, nervousness, utter exhaustion and hospitalization.

It took Kilgore five minutes of conversation with the patient to get this information, yet what did he find when he examined her aluminum encased hospital record? Five and a half pages of closely written matter comprised under twenty-eight captions, all neatly underlined with red ink. He toiled in vain through the history for bits of useful information. The marital history yielded the information that the woman had four children but contained nothing about the fiasco of her eldest son. Kilgore summarized by stating that this is a gross example of unrestrained standardization, stereotypism and perfunctoriness in history taking. It does bring forcibly to attention the importance of delving into the background of the patient's complaint and establishing in chronologic order the events leading up to it.

In making his complaint to the physician the patient may be prone to present bizarre and indefinite symptoms along with clinically significant factual data. It must be realized that the average patient knows little or nothing about things medical and that his answer to questions may unintentionally be misleading. It is the difficult but important duty of the physician to analyze each complaint carefully, so that any suspicion of organic disease as a cause of each symptom can be excluded or confirmed. Salzstein¹ summarized the task well when he stated that a physician must be able to extract from the wandering, worried, frequently uneducated and unclassified impressions of a patient a cleancut story without bias and free from leading inquiry. Stewart² stated that he thinks of a physician as an attorney who is collecting evidence and examining a witness. He must not take what is given him but must hunt for what he needs, sifting the essential story out of a mass of fiction and extraneous fact. Cavanaugh³ stated that the art of selecting important data makes the diagnosis of a difficult case a clear and easy process.

PHYSICAL EXAMINATION

When the major complaint has been analyzed thoroughly and notes have been made concerning factual data obtained, or when it

1. Salzstein, H. C.: *The Art of Medical History Taking*, J. Michigan M. Soc. 34: 762-766 (Dec.) 1935.

2. Stewart, D. A.: *Medical Histories and History Writing*, with Special Reference to Tuberculosis, Wisconsin M. J. 30: 257-260 (April) 1931.

3. Cavanaugh, J. A.: *Why Histories?* Illinois M. J. 72: 143-145 (Aug.) 1937.

becomes apparent that the patient complains of many conditions, the physical examination should be started. While the physician is examining the patient, he should ask specific questions regarding symptoms referable to every part of the body. If the questions are properly put, a denial of symptoms referable to together with normal physical phenomena concerning the part in question should exclude organic disease reasonably well. If an answer is doubtful, the physician must analyze the symptom carefully to determine whether or not it is of clinical significance. It must not be forgotten that patients whose major distressing symptoms are due to functional disease may also have organic disease and that the symptoms of the latter may be elicited only by careful direct questioning.

Examining a patient before composing and recording his history enables one to evaluate more accurately symptoms the significance of which may have been obscure before the examination. It also enables one to give each symptom of which the patient may complain a place in the history corresponding to and commensurate with its diagnostic importance and to correlate or demonstrate absence of correlation between the symptoms and the conditions found.

The value of a clinical history and the ease with which it can be elicited vary with different types of patients. Dunn⁷ pointed out that the variation in the consistency of answers given by a patient may depend somewhat on his mental or physical condition as well as on who puts the question and how it is put. He adds that it is essential for the physician to be able to frame and expand questions so that they produce correct and fruitful answers.

I have chosen to divide into four main groups patients whose histories may be particularly difficult and time consuming to elicit. It should be helpful to consider the difficulties presented by each group, and methods by which these difficulties can be surmounted.

FOUR DIFFICULT GROUPS

Foreigners who can speak little or no English constitute the first group. When a physician has the problem of such a patient to solve on a busy day, the temptation may be to spend little time attempting to get the history and proceed with the physical examination. This method is likely to lead to diagnostic inaccuracies. There is just one way that I know of to do justice to the problem of such a patient, and that is to take the history through an interpreter, spending as much time as may be necessary to analyze and evaluate the patient's complaint.

Poor observers constitute the second group. This includes individuals of stolid temperament who usually do not consult the physician until they are disabled by their illness. Often they remember little if anything concerning symptoms antedating the incident leading to their disability. For example, a man came for examination because of a recent gastrointestinal hemorrhage. On direct questioning he was unable to give symptoms suggesting duodenal ulcer, gallbladder colic or other organic disease of the gastrointestinal system, yet at exploration he was found to have not only a duodenal ulcer but also subacute cholecystitis with cholelithiasis. Another man came because, for one week, he had been vomiting almost everything that he ate. He was a farmer, had always worked hard up to one week prior to his examination, and on direct questioning remembered only vaguely some mild indigestion of about thirty years' duration about which he had never done anything. At exploration a chronic duodenal ulcer with almost complete pyloric obstruction was found.

STOLID INDIVIDUALS

In attempting to elicit a history from this type of individual the physician may feel slightly irritated because, although he may be certain that the patient has organic disease and that he should have had symptoms antedating his disability, the patient answers all his direct questions negatively. However, if the physician recognizes the existence of this group of stolid individuals who do not complain until they are practically disabled, he will not be impatient with them for being unable to remember symptoms that they have not felt because of their phlegmatic, insensitive nervous systems.

The value of the history of such patients will be less than that of the average individual, and one may be compelled to rely more on the physical examination and especially laboratory studies in arriving at a diagnosis.

Multiple complainers, many of whom are elderly, constitute the third group. These patients usually are very talkative and may be even garrulous. They may begin their story in a modest way, but as they sense the physician's increasing interest and sympathy the number of complaints increases until every part of the body may become involved. If subjected to direct questioning, every inquiry may be answered affirmatively. They seem fearful of forgetting to mention some detail which usually is of no consequence. They often come to the physician mainly to be sure that no serious disease is developing insidiously. When asked if they are unable to carry on their usual activities on account of the conditions of which they complain, they state that they have to keep going in spite of their difficulties or they say that

7. Dunn, H. L.: Practical Experiments in What Actually Constitutes a Good Clinical Record, *Minnesota Med.* 17:589-591 (Oct.) 1931.

they shouldn't stay up and around but they do keep going by sheer will power. Conditions of which such patients complain often have been of long duration. When asked what crystallized their decision to come just when they did, they may reply "Because I had a chance to come with a friend; because my local physician could find nothing wrong with me and suggested that I come for your opinion; because my husband got tired of hearing me complain."

As soon as a physician discovers that he has a patient of this type, he should proceed at once to the physical examination. It is said that Sir Jonathan Hutchinson⁸ would always hastily thrust a thermometer into the mouth of any woman who attempted to tell him about her illness. However, I believe that these patients are better pleased if allowed to tell their story. Examining them while they talk, the physician not only can save much time but also better evaluate such complaints.

Patients of this type usually are pleased at the conclusion of their examination if they can be assured that no organic disease is present and their symptoms can be explained adequately on the basis of a hypersensitive nervous system secondary to nervous exhaustion or cerebral arteriosclerosis.

VAGUE COMPLAINTS

Vague complainers constitute the fourth group. This includes a large group of patients who often present only one major symptom. Their description of this symptom, however, is usually bizarre, meager and not characteristic of any clinical syndrome. In attempting to get what they consider an unbiased opinion, or simply on account of prudery, they may withhold information that might enable the physician immediately to get the proper perspective of the problem. It is of great importance for the physician to find out all the factors which may be behind such a complaint and this can be accomplished only by tactful inquiry. Let us consider some of the factors which crystallize a patient's decision to come to a physician with such a complaint:

Fear of disease often is the real problem behind a vague complaint, although patients rarely will admit it without direct questioning. I usually put the question like this: "Do you seek medical counsel because of the intensity of your distress or mainly because of fear of what might be developing?"

Undisabling, more or less constant soreness or pain, not infrequently of long duration, is probably the most common symptom associated with fear of disease. For example, the basic problem of a patient with a major complaint of such pain in the head may be fear of a stroke

or brain tumor. If the pain is in the chest, the fear may be of heart disease; if in the breast, of cancer, and if in the abdomen, of appendicitis. The patient often develops his fear complex after the death of a relative or friend has been caused by the disease feared.

A desire to have the diagnosis of another physician verified is also a factor commonly behind a vague complaint. Patients who come for examination with this objective can be divided into two groups: those who do not disclose the real objective of their examination unless a direct question regarding the diagnosis elsewhere is put to them, and those who name the diagnosis given elsewhere in citing their complaint. Patients of either group present difficulties for the physician in his efforts to elicit pertinent clinical data.

The objective of a patient who comes to a physician to have a diagnosis given elsewhere verified, without disclosing this fact, should be suspected by the physician because of the non-descript nature of the complaint. When the physician's suspicion is aroused, he should ask the patient if he has had examinations elsewhere and, if so, what diagnoses were given him. If a patient has an examination just to check on a diagnosis given elsewhere, it is of the utmost importance to the physician to know what this diagnosis was, so that special attention can be given this problem in planning the examination.

For example, the real objective of a patient with a bizarre pain in the right upper part of the abdomen may be to secure verification of a diagnosis of tuberculous right kidney given elsewhere. He may disclose no urologic symptoms, and there may be neither physical nor laboratory evidence warranting urologic investigation. If the physician did not find out about this diagnosis given elsewhere, the patient would not be able to get a satisfactory opinion concerning his major problem.

PATIENTS WITHHOLD INFORMATION

Some patients purposely withhold pertinent information and the physician must be quick to sense this. I remember a middle aged woman who gave a history that immediately suggested the diagnosis of uterine leiomyoma, and the physical examination confirmed this diagnosis. However, there was something about the way she related her symptoms which suggested that she might be withholding some information. When questioned as to why she had come for examination just when she did come and what her local physician's diagnosis had been, she stated frankly that he had told her a few days previously that she had a cancer of the sigmoid colon and she came to find out about it. Proctoscopic examination disclosed the presence of a rectosigmoid carcinoma, although she com-

8. Hutchinson, Jonathan, quoted by Ward.²

plained of no symptoms that could not be attributed to her large uterine leiomyomas.

With the patient who cites the diagnosis given elsewhere as his main complaint, the physician's major problem is to elicit if possible from the patient the symptoms on the basis of which this diagnosis was made. For example, the patient may complain of an "infected kidney." The physician should ask "Of what symptoms were you complaining or in what way were you suffering at the time you saw your physician when this diagnosis was made?" He may find out that the patient's urinary symptoms started several months before, that the patient had no urinary symptoms for the past six weeks and that his real objective was now to determine the present status of renal function.

Often it is very difficult to elicit a recital of the symptoms and disability caused by the alleged disease without irritating the patient. Especially is this task difficult if a patient has been to several different physicians who have given conflicting opinions. If the physician's attitude bespeaks incredulity, the patient is likely to be antagonized; whereas, if his attitude bespeaks kindness and sympathy, the patient is likely to disclose willingly the symptoms that led his physician at home to incriminate various organs.

MENTAL DISEASE

Another problem, not infrequently the basis of a vague complaint, is mental disease. The physician may have to talk to the patient for a long time before he can get a clue, in the form of a delusion, as to what the problem really is. Strangely enough, the relative who accompanies the patient often will not disclose the delusional state of the patient, even if he is aware of it, but chooses rather to have the physician find it out for himself if he can.

One good way to get at such a problem is to ask the patient if he came for an examination of his own accord or simply because his relatives wanted him to have an examination. If the latter is his answer, the possibility of mental disease as a cause of the symptoms is a reasonable suspicion.

Not long ago I saw a patient whose main complaint was that she could not eat. Her sister had brought her almost by force, for the examination. The patient was sure that she would not be helped. She seemed unable to explain just why she could not eat. She would not partake of all of the Ewald test meal and refused to swallow the Rehfuß tube. The sister was asked to leave the consultation room and the patient was questioned further, especially as to why she was not able to eat all of the Ewald meal. She stated that she could not get rid of it if she did. When asked to elucidate further she stated that she had neither kidneys nor stomach and that therefore there was no

way for the food and water to be eliminated. She also thought that many other organs had wasted away. Her sister was fully aware of this delusional state yet did not reveal the fact, else my problem would have been greatly simplified. The physician always should keep in mind the possibility of mental disease as the explanation of a vague complaint.

SUGGESTIONS ON COMPOSING HISTORIES

If the methods described have been employed in eliciting a patient's complaint, the task of composing and recording the data obtained, in the form of a clinical history which has diagnostic value, is not difficult. However, there are a few suggestions concerning the composing and recording of histories which, if followed, will increase their value appreciably:

Keep irrelevant data out of the history so that its length can be kept at a minimum. Often, because of previous instruction in medical school, the recently graduated physician is inclined to record accurately every symptom of which the patient complains instead of analyzing each symptom to determine whether or not the patient actually is suffering from it. For example, the patient may state that he is short of breath on physical exertion yet analysis of this complaint may reveal that he can do the same things that the average individual of his age and weight can do without getting short of breath. Salzstein stated that two or three closely written pages of variegated complaints may represent much effort but do not necessarily indicate completeness or accuracy and probably do not permit logical deductions. Stewart emphasized the importance of separating rigidly fact from the patient's fanciful explanation of fact, or even one's own. Distinguish clearly between what he did have, what he said he had, and what his attending physician said he had in that obscure illness twenty years ago. Stewart added that a disorderly jumble of what the patient said is fit only for the wastebasket. The data that the patient gives should be used, but the physician should analyze and edit it before incorporating it in the clinical history. Remember that the completed history is the physician's workmanship and not the patient's.

When the physician has to deal with a multiple complainer whose symptoms are entirely functional, the history should deal mainly with the events leading up to their development, and the various complaints themselves should simply be enumerated. There is no diagnostic value in the recorded analysis of thirteen complaints each of which is of neurogenic origin.

Finally, after the history has been composed and recorded, forgetting if possible the difficulty with which it was elicited, one should read it over carefully before making a tentative diag-

nosis. The arduousness of its elicitation in some cases may leave a stronger impression than the factual data themselves and thus may lead the physician to erroneous conclusions if he does not reconsider the data in the history before summarizing his impression of the case.

CONCLUSIONS

1. In eliciting a clinical history the physician should achieve three main objectives: He must acquire pertinent clinical data that will lead to a correct diagnosis; he must perform the task with as much speed as possible; he must strive to please each patient.

2. In order that the physician may get the proper evaluation and perspective of a patient's problem, the following four points should be

established early in the process of eliciting a clinical history: the major complaint, its duration, what crystallized the patient's decision to undergo the examination just when he did, and whether or not the condition concerning which the major complaint is made has disabled the patient.

3. Patients whose histories may be particularly difficult and time consuming to elicit can be divided into the following four groups: foreigners who speak little or no English, poor observers, multiple complainers and vague complainers.

4. The fundamental problem of a vague complainer often is one of the following: fear of disease, a desire to obtain verification of a diagnosis given elsewhere, and mental disease.

Comments and Reviews

THE ROAD OF THE MEDICINE MAN

Abridgment of the Convocation Address, delivered by Dr. Albert E. Rector, President, State Medical Society of Wisconsin, at Marquette University School of Medicine, Milwaukee, Sept. 26, 1938, and published in the Marquette Medical Review, January 1939.

From an experience of forty-five years in our profession, I hope to make some observations that may be helpful to you. The example of three practitioners of medicine inspired me to enter this field, none of whom accumulated financial independence or ever performed an appendectomy or a tonsillectomy. They lived their professional lives in the same community and received its approval of their services. Your educational advantages make opportunities for you never dreamed of in my student days.

Medicine has widely expanded so that you have the choice of many specialized practices. However, you must first broaden yourself in the general field of medicine. The really broad physician is the conscientious man in general practice who has learned the art of practice and become a teacher in the art of living. These acquired abilities often outrank even the science of medicine in meeting the needs of the public.

You should carry the marks of the educated, ethical man who adapts his personality to the people he serves. You must have the ability to be at ease in the different kinds of homes where you are called so that you may gain the patient's confidence and establish a friendly relationship that the family too may feel at ease during your visit. Your personality should leave in every patient and family contact something of pleasure that helps remove the worries of illness. A casual scientific contact cannot give all that the sick requires. You

must give something of yourself to patients other than professional advice. This is implied in the recent report of a committee of the State Medical Society of Wisconsin appointed to study health service:

The committee feels that the very nature of professional education today tends toward producing physicians who are so engrossed in the technical and scientific phases of medicine that they may lose the human touch. There are no untouchables in disease, and there must be none in medicine. The role of the family physician as the friendly counselor, adviser, and even in that little considered but all important field of encouraging both patient and family, is of extreme importance. Attention is directed to this necessary quality, for, should it be lost, the practitioner will divorce himself from the obligation of the true physician for which the demand and need are as great today as at any time in history.

Some of the qualifications of the family physician are:

1. He must have scientific training and the ability to apply practical knowledge.

2. He must have an earnest desire for advancement in his profession. He must be associated with the local medical society.

3. He should show an interest in community affairs.

4. He must be honest, a man of religion, must not criticize professional associates and should reserve his criticism of scientific subjects for medical meetings and scientific publications.

5. He must subordinate monetary gain to scientific advancement.

With these qualifications he will be able to care for 80 per cent of his community's sick and also do public health work.

Have pride in your work. Your patients will respect the end results on about the same basis as you render your own personal judgment.

They appraise your worth and make keen deductions of your ability.

The public should be made more aware of the implications that are being forced on them by sociologists and governments. You must watch with care the economics of your vocation. Medicine is not a commodity that can be sold. It is a service to protect the public health and care for the sick. In countries where the control of medicine has passed into the hands of government and lay directors, there is a rise in disease in proportion to this domination.

The State Medical Society of Wisconsin from time to time places its seal of approval on doctors who have given meritorious service. This emblem has been given to a few physicians not because of their scientific attainments but because of their devoted service. The emblem has been given to one woman, a country doctor all her life and for thirty-six years secretary to her county medical society. It has been given to a member of the profession present with us today for service to medicine in teaching and training others.

EFFICIENCY OF MEDICAL SERVICE

In the controversy now before the public relative to the type and method of delivery of medical service, I challenge critics to compare the efficiency of all other vocations with that of American medicine. The medical profession has advanced scientifically and has increased its public health efficiency and cooperation with both local and state governments. It has cared for the sick when the family failed, when charity failed, when local, state and federal governments failed in their duty to the unfortunates who were justly their wards. It has delivered a better type of medical care than was furnished by the government in such other types of necessities as food, shelter and clothing, and with less noise and less complaint, and largely with little or no remuneration. The medical profession during the last ten years has been the second largest contributor to medical needs, being surpassed thus only by the federal government. It has contributed, according to conservative studies, \$1,000,000 a day during the past seven or eight years. When you compare thus our powerful government, and the medical profession with only 150,000 members in practice, this fact is beyond comprehension.

Disregarding these facts, the proponents of change insist on legislation to further socialize American medicine. The practice of medicine is not a commodity that can be resold at a profit. It is a service that can be delivered only by the properly trained individual.

Having entered the profession, you must dedicate your life to the service it alone can render.

AMERICAN RESPONSIBILITIES FOR THE UNIVERSITY

Abridgment of an address by Dr. Alan Gregg before the Federation of Societies for Experimental Biology, Toronto, April 28, and published in Science, June 23, 1939.

For sixteen years I have had occasion to visit medical schools and institutes of medical research in some thirty countries. In the variety thus encountered, one is reminded of a saying of Oscar Wilde: "When you break the little laws the big laws begin to operate," for out of so many contradictions and differing practices emerge certain underlying principles.

Now, I would like to ask, are we prepared in North America to assume responsibility for the maintenance and continuation of one of the greatest traditions of western Europe, the university? Are we free to select the best there is in the university tradition and cherish it?

An arresting story is told of the tercentenary of Harvard. In three separate instances European delegates to the tercentenary remarked privately to their friends: "I came to this celebration with a heavy heart. Our priceless heritage, the university, is in the gravest peril in Europe. But what I have seen here gives me hope again, for I have seen that it can go on in North America." To match this faith let us ask ourselves the question "Are we fully prepared to carry on if need be?" For that may be our greatest task in the next twenty years.

CHANGING ATTITUDE TOWARD EUROPEAN UNIVERSITIES

Before 1914 in North America we regarded the universities in Europe with earnest respect. Indeed there was admiration and the flattery of imitation. Many of our superior students sought and found in Europe intellectual habit—personal independence, intellectual method—thoroughness and the conviction that there was an opportunity for each to add to the scholarships of the world. Relationships almost filial in their devotion grew up between great teachers and eager Canadian and American disciples. And of peculiar importance and value there spread over our university life that wonderful openmindedness and unself-conscious receptivity which always characterizes ingenuous humility and true modesty. We weren't ashamed to learn nor afraid to try.

From 1914 to 1934 circumstances and attitude have changed. The flow of graduate students to Europe has much diminished. Europe has had less comparatively to offer: its university facilities often seem niggardly, its professors overloaded and impoverished. Confidence and leadership are not in the air. On this side of the Atlantic, university buildings, facilities,

endowments and teaching loads have increased. We have made some substantial additions to the world's store of knowledge. Of all that is worth attention in the European universities we may have accepted only a part, and of what we have accepted only a part in turn may survive. Higher education in North America has grown in an environment peculiar and at variance with the European milieu. The position of the intellectual in Europe may be affected by the fact that in every European capital there is a great university. In America the political capital is not the place of a great university.

CHARACTERISTICS OF AMERICAN UNIVERSITIES

Another characteristic in the North American scene: Underlying higher education here we have forms of secondary education which prepare our students for advanced work in the universities less adequately than their analogies in Europe. For their objectives and for society generally our secondary schools may do a passable job, but for the purposes of the university the secondary schools in America leave much to be desired. One of the reasons must be the relative absence of family ambition and pressure on young people of the secondary school age. On the suburban train out from Paris I used to see a French father and his young son, who used that precious twenty-five minutes in a regular and earnest lesson in English. Later in a similar commuter's train out of New York I saw one time a similar father and son, and this time the father was reading the stock reports and the boy was reading the "funnies."

Historically, our universities grew out of the colleges. The colleges were in the main sectarian enterprises to produce teachers and preachers. There was more pressure for the graduates, teachers and preachers to be numerous than to be excellent, and this pressure had also a flavor of sectarian competition, and so grew up the tradition that the college professor's moral and religious duty was to teach, and this well-nigh to the exclusion of scholarship and participation in self government or associate living. In some of the colleges today there is a measure of sectarian stubbornness, narrowness and pretension which knows no better standard for self comparison than the record of some nearby rival.

DILUTION OF SCHOLARSHIP

Add to this preoccupation with the teaching load the aura of political and social approval expressed in the phrase "equality of opportunity" and the staggering mass of poorly prepared students which have been crowding the colleges and universities and you have a dilution of scholarship which is no better than edema. It will "pit on pressure." As in planting trees too close together, the equality of opportunity is not as important as the nature of the

opportunity and relief from unreasonable circumstances. Our universities have accepted so huge a burden of teaching that there is a serious discrepancy in many institutions between the tacit understandings on the campus and the explicit claims and purposes in the catalogs.

TESTS OF A UNIVERSITY

There is a better test than numbers, than equality of opportunity, than the moral duty of teaching. We should rather judge a university or indeed any form of human association by what kind of a life it permits, encourages and rewards. We are flooded by students, by poorly prepared students. We encourage them by our methods, and our tradition of being teachers foremost has accustomed us to being preoccupied with what we are really giving the students. We are sentimental about it. We give till it hurts—till it hurts the student. We should be more preoccupied with the social and intellectual climate created by the university—a social and intellectual climate in which the creative powers of scholars will flourish. The Scandinavians, when they build a laboratory, provide specifically a room or two for the emeritus professor. What a wise understanding of what retirement could mean! I do not retire at 65, nor does the counsel and contact with men above that age cease to be valuable to me. There should be more appreciation of the concept of the university as a place where any person's genius for the scholarly life is cherished. The system of dining in hall in the English university has something we can't capture in hurried cafeteria lunches at the Faculty Club. There is a leisureliness and an equality among fellows dining in a hall which enables them to estimate and experience one another as human beings. That is precious. How soon will we realize that we could pay more attention to each other and thus to the example we set our students?

THE OLD WORLD'S INTEREST IN QUALITY

Equality is the best condition for securing freedom, and whatever helps to make your colleague feel himself your equal is precious to him and to you and to the life of the university. The judicial mind, self criticism, the readiness to discuss and dispute without dogmatism—and then tolerance, dignity and fair play—all these are exquisitely desirable in order that freedom and variety be given a chance to prove their value. Such a theory of the élite and of equality can be conveyed only by example and experience—lectures, books, exhortations and speeches are quite useless. I miss the Old World's interest in quality—and their grave expectations of what an élite may be relied on to do. We take, compared with Europeans, a motherly interest in their difficulties instead of a fatherly

interest in their trials of strength. We reward the élite with distrust and a heavy routine instead of with freedom, expectation and responsibility. Not long ago a French scholar with no university connections wrote three excellent books in the field of medieval history. In recognition of his ability he was offered a professorship at the Collège de France. He accepted. He called on a colleague in the college to learn a little more of what might be expected of him. After an hour of inconsequential talk he got down to his main inquiry. "Tell me," he said, "what are my duties at the Collège de France?" The reply was "Ask the janitor. He knows when the rooms are heated, lighted and available. For it is the tradition at the Collège de France to select persons who know how to lead in their fields better than any one else can tell them, and we leave that problem to the men to solve as they see fit."

DIGNITY OF SCHOLAR'S POSITION ABROAD

Now such confidence in superior human beings involves a respect for the individual and a naturalism that are remote from the lire-and-fire atmosphere pervading the college and many a university preoccupied with teaching schedules and processing the student. The professor abroad is selected with more deliberate and thorough discrimination than is yet the common tradition here, and then rewarded with a greater measure of confidence. There is a certain dignity in the scholar's position in Europe; it gives us all pause. I think it derives from the stability of his situation. What have we in North America to link the university to society in general, to allow occasional but thorough contemporary evaluation of the universities' work? What are the means of responsible criticism by society at large? The university president? The public relations vice president or office? The alumni? The regents or trustees? If you doubt the importance of the effect of society on the university, think of the danger that lay in the German universities being so close to the government. The professors were in most cases government employees, and when a political group seized the power of the government the professors were included among the newly acquired possessions. We need further reflection on the ways in which society can wisely criticize the university and ways in which the university could sense and in some cases implement such criticism.

SUMMARY

The North American scene is characterized by a cultural homogeneity that overwhelms dissent and puts protest on the defensive. Our universities are divorced from national policy and practical affairs, and this heightens a policy to emphasize learning by symbols rather than by experience and makes the word "academic"

an equivalent for "unpractical." Our secondary education is inadequate not for its own objectives but certainly so for the needs of the university. We overemphasize the importance of teaching and so rob the student of experience and of practice in the strategy of his existence. And, lastly, we have too many students, and this dilutes the quality of university experience for those best qualified to receive it.

I think experience in Europe would make you wish we had emphasis on the conception of the university as a place where a certain kind of living and example are best realized. You'd find a large measure in Europe of interest of the élite in their responsibilities, an interest in quality, be it ever so rare, and a respect for the individual—his vagaries as well as his excellences. You might come to see, as I have, that there are advantages in the measure of self direction and self management of the European universities and in the somewhat austere simplicity of the European scholar's life. You'd return reflecting on the significance of the university to society and the responsibility and reflective criticism each of the other. I have ventured to call attention to functions I should like to see more of if we in the universities are to be in part responsible for maintaining and cherishing delight in beauty, enjoyment of reason and joy in the skills of living.

STUDY OF APPLICANTS FOR ADMISSION TO 1938 FRESHMAN CLASS

Condensation of an article by Fred C. Zapffe, M.D., published in the July 1939 issue of the Journal of the Association of American Medical Colleges.

The Commission on Medical Education in 1926 financed a study of applicants for admission to medical colleges of the United States. The last study made by this commission included the 1929 class. The Association of American Medical Colleges in 1932 decided that the study was to be resumed, and since then it has been one of the main activities of that association. This study provides data on the number of applicants each year who sought admission to medical colleges, how many were accepted or rejected with the reasons for rejection, and the number of applications made by individuals; it is also a means to detect fraud. While the number of applicants for admission to medical colleges has varied with the economic conditions of the country, the number of applications has steadily increased. Medical colleges on the whole are accepting fewer applicants, and those accepted are better prepared for the study of medicine. From 1933 to 1938 the number of applications had increased by about 6,500, although the number of applicants through these years remained about the same, 12,131 as against 12,128. The

number of single applicants (that is, those who make only one application), decreased nearly 20 per cent since 1933, while those who made more than one application (multiple applicants) increased about 20 per cent. It is easy to understand why the number of multiple applicants increased, but it is not easy to account for the decrease in the number of single applicants. Most medical colleges have accepted fewer students since 1934.

Women are making a greater effort to enter medicine. The number of women applicants since 1933 has increased by about 26 per cent, and the number of applications made by them has increased by 48 per cent. The acceptances for women applicants has decreased from 62.3 per cent in 1933 to 50 per cent in 1938. There was in this period an increase of nearly 100 per cent of "multiple" applicants, but the number of "single" women applicants was practically the same in 1938 as it was in 1933. The number of women medical students is not increasing very much.

Only 6.6 per cent of the applicants for admission to medical colleges in 1938 had less than three years of college work and of that group 54.4 per cent were accepted. Twenty-four and a half per cent of the applicants for admission to medical colleges in 1938 had from three to four years of college work, and of this group 56.7 per cent were accepted. A hazardous group is the one comprising applicants who had been in college for four or more years but who had not received a degree. The study of student accomplishment shows that they do badly in medical school.

The rejection of applicants may be based on several points. The class may be full; a refusal of acceptance for this reason cannot be regarded against the applicant. The rejection may be based on inadequate credentials; about 3 per cent of all applicants fall into this classification. Rejection may be based on poor scholarship or personality; about 30 per cent of all applicants fall into this group. Some medical colleges accept only A and B students, while others accept as low as C students. Only two medical colleges require, with certain specifications, that

an applicant have a college degree for admission; three or four other medical colleges select only those who have a college degree. However, more than 60 per cent of the 1938-1939 freshman class of medical colleges in the United States had a degree, and only 4 per cent of them had less than three years of preparation.

Passing on applications is an enormous task for some medical schools. Seven colleges considered more than 1,000 applications, and one school considered 1,393, of which 214 were accepted. Some state schools will not consider an applicant who is a nonresident. One school accepts only applicants who are members of the religious group which operates the school. Fewer applicants were accepted in 1938 than in preceding years. The total number of applicants enrolled in the seventy-seven medical colleges in the United States in the fall of 1938 was 5,582, not including all repeaters. The total number of applicants accepted was 6,223; 541 accepted applicants did not matriculate.

MULTIPLE APPLICANTS

There were 5,882 multiple applicants, who made 30,000 applications, an average of six per applicant. More than ten applications were made by 590 applicants; one applicant made forty-three applications.

New York State, with about one tenth of the population in the United States, supplied 16.6 per cent of the applicants. Pennsylvania, with about one thirteenth of the total population, supplied about 8.5 per cent of the applicants. These two states, with about one sixth of the total population, supplied about 25 per cent of the applicants. Nineteen foreign countries were represented by fifty-five applicants for admission in 1938.

Judging by past experience, less than 5,000 of the freshman class in medical colleges will graduate; nearly 100 will not go further than the freshman year, many will fail and be dropped, some will find that they do not care for medicine, some will become too ill to continue, a very few will drop out to return to college and some will be unable to finance their medical education.

Correspondence

THE QUESTION CONCERNING ABORTIONS

To the Editor:—I was much interested in the Student Section in *THE JOURNAL*, November 25, and especially in the questionnaire on page 2005. Do these answers represent an average cross section of the opinions of the medical youth of today? The answer to question 18 shocked me. Perhaps I am an old timer, having been fifty years in the profession. My father also was a physician (Edinburgh 1856). He was taught and he taught me that any interference

with the course of pregnancy was nothing less than murder.

To think that, if legal, 68 per cent of the medical students of today would be willing to perform abortions on married or unmarried women, except after consultation and for pathologic reasons, speaks badly for the moral or religious ideals of these young people. In my opinion, the place to cure this condition is in the medical schools, which should lead their students in the right direction.

HENRY WALLACE, M.D., New York.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Full Tuition for Six Students

The anonymous gift made last year by a friend of Columbia University College of Physicians and Surgeons, New York, of full tuition for six students for the entire four year course has been repeated this year. Last year at Columbia ninety-one students were employed in steady positions as a means of helping themselves through school, while 136 students had temporary jobs. These figures were the highest since the opening of the employment file in the dean's office seven years ago. In fact, 44 per cent of the students had employment, 25 per cent received scholarships and 5 per cent received loans.

Tulane Juniors Awarded Plaque

A handsome plaque was awarded to the junior medical class at Tulane University of Louisiana School of Medicine, New Orleans, for winning the greatest number of points in intramural competition during the year 1938-1939. The class advanced to the semifinals in both basketball and softball and won the touch football championship. Among the principal players of the class were Harold R. Goldfarb, Harry C. Tiller, Jack Hyman, Henry C. Hudson and Arthur Grady Williams Jr.

Louisiana's *Tiger*—A Correction

For eight consecutive years, the medical students of Louisiana State University School of Medicine, New Orleans, have published a weekly paper known as *The Tiger*, Journal of the School of Medicine, Louisiana State University. The Student Section of THE JOURNAL, November 25, page 2011, erroneously credited *The Tiger* to Tulane University of Louisiana School of Medicine. *The Tiger* is, the editors believe, the only weekly paper in this country published by medical students. It has three principal objectives: (1) to cover all news happenings at the school of medicine and report other local and general medical news; (2) to publish scientific contributions from members of the faculty and student body, and (3) to promote various extracurricular activities such as intramural sports and chess tournaments. The staff of *The Tiger* is drawn entirely from the student body of Louisiana State University School of Medicine, with the exception of the medical editor (who serves as faculty adviser), the medical artist and the assistant medical artist.

Fees at Minnesota

The quarterly fee for the medical course at the University of Minnesota Medical School, Minneapolis, is \$75 for residents of Minnesota and \$125 for non-residents, payable at the beginning of each quarter. No fee is charged in the medical school for the final hospital or advanced laboratory (fifth) year. The registrar of the university determines the status of applicants as to residence.

Applicants who are not legal residents of Minnesota must pay an application fee of \$5 at the time of application. This will be credited to the tuition for the first quarter in the case of successful applicants but will not be refunded to those whose applications are rejected.

In addition, each student is charged an incidental fee of \$8.50 each quarter. Laboratory fees may be instituted or modified at any time by action of the board of regents.

A matriculation deposit of \$15 (\$5 for women students) is required, payable with the tuition of the first quarter in residence, as a guaranty for the return and protection of university materials and equipment, the remainder to be refunded on the student's withdrawal, failure to return for any succeeding quarter, or graduation.

Students who take less than the regular course of study may arrange their fees at the rate of \$3.25 (non-residents \$5.75) for each weekly clock hour per quarter.

Repetition of a course requires the payment of additional fees. A graduation fee of \$7.50 is charged for each degree conferred.

Late registration: The fee for the privilege of late registration, late change of registration or late payment of fees shall be \$2 prior to the day on which classes begin, on and after which the fee increases at the rate of \$1 a day, provided no student shall pay more than \$10 in fees for such privileges in any one quarter.

Prizes Offered at Minnesota

The Minneapolis Surgical Society offers a first prize of \$75 and a second prize of \$25 to those members of the senior class of the University of Minnesota Medical School, Minneapolis, or those serving the first year of their internships in Minneapolis hospitals who write the best papers in some field of clinical surgery. These papers must be in the hands of the secretary of the society in March.

The Southern Minnesota Medical Association offers an annual prize of \$100 and a medal to the most representative student or students in the senior class of the university. This award is made on the basis of the scholarship, extracurricular activity and character of the student, as well as on the general excellence of the thesis.

The Rollin E. Cutts Prize in Surgery is awarded in the form of a gold medal to that member of the senior class who presents the best thesis based on original work in a surgical subject.

Premedical Students Visit School

A group of forty-five premedical students in charge of their professor of physiology, J. H. Brownback of Ursinus College, Collegeville, Pa., visited Temple University School of Medicine, Philadelphia, November 30. They were shown about the laboratories and clinics by Dr. Morton J. Oppenheimer, assistant professor of physiology at Temple and an alumnus of Ursinus College.

The William Osler Society at Tufts

The William Osler Society, a student honor organization at Tufts College Medical School, Boston, has announced the names of the following newly appointed members from the fourth year class: Harvey Katz, Gertrude A. Rogers, Elmer L. Grimes and Emil J. Koenig Jr.; from the third year class: Carroll Bryant Jr., George A. Dodge II, Clement S. Dwyer, Herbert F. Hager, Robert S. Hagen, Alfred Kant and Arthur N. Kelly.

Scholarships and Prizes at University of Oregon

At the University of Oregon Medical School, Portland, the Noble Wiley Jones Pathology Research Fellowship, consisting of the interest on \$5,000, is awarded annually to a medical student on the basis of scholastic

ability, training in pathology and interest in the work. The Henry Waldo Coe Prize is awarded annually to a second, third or fourth year student who presents an essay on a medical subject exhibiting superiority and originality in composition. This prize is the interest on \$1,000. The Pohl Memorial Fellowship is awarded to a student of promise in the field of medicine. With authorization from the legislature, the state board of higher education awards annually a number of scholarships to students in the institutions of the state system who rank high in scholastic attainment and need financial assistance. These scholarships cover tuition. The recipients must pay the building fee, the matriculation fee and special fees. Application should be sent to the dean's office not later than May 15.

Indiana Interns Appointed

All of the 102 members of the last graduating class of Indiana University School of Medicine, Indianapolis, who applied for internships received appointments. The two graduates who did not make applications for internships had other plans. Sixty-four of the recent graduates will remain in Indianapolis for their internships, and eleven will intern in hospitals in Muncie, South Bend, Terre Haute, Lafayette and Hammond. The other twenty-seven graduates will intern in hospitals in Ohio, Illinois, California, Colorado, Minnesota, Missouri, New York, Louisiana, Canada, Pennsylvania, Washington, New Jersey and Wisconsin.

The dean of Indiana University School of Medicine, Indianapolis, has announced that, among the twenty-eight recent graduates appointed to serve as interns in Indiana University Medical Center Hospitals in 1940-1941 will be the following six graduates from other states: O. Will Allison, Danville, Ill., Jefferson Medical College of Philadelphia; Maurice A. Canon, Amarillo, Texas, University of Texas Faculty of Medicine; John N. Carnes, Gallipolis, Ohio, Ohio State University College of Medicine; George P. Smith, Denver, University of Colorado School of Medicine; Dwain N. Walcher, Nokomis, Ill., University of Chicago, and Henry J. Winsauer, Kohler, Wis., University of Wisconsin Medical School.

Graduate Training for Residents at Columbia

A large number of residents in the hospitals affiliated with Columbia University College of Physicians and Surgeons, New York, last year took regular instruction in medical sciences in the graduate laboratories of the school or were otherwise engaged in work toward the degree of doctor of medical science. Some hospital residents received science instruction in various hospitals. As this program of graduate training evolves, an increasing number of residents will be enrolled. This program is independent of that of undergraduate students, but every effort is made to integrate the needs of both groups of students and to secure full coordination of the staffs of the clinical and scientific departments of the medical school. An effort is made to regard the residents as graduate students in the university sense. They are placed largely on their own responsibility for learning the subjects; instruction is by means of individual work, conferences, laboratory experiments, investigation of problems, seminars, and the reading of original articles. Clinical men on the staffs of the hospitals take part in the exercises and assist in laboratory instruction. No two services have the same arrangement and distribution of time. Some services require the residents to report ahead of the time of their appointment in order to obtain the instruction offered in the medical sciences; others believe that the most effective way of coordinating medical science instruction and clinical training

is to offer certain blocks of time for laboratory investigation throughout the residency period. In several instances the medical science training is provided in the evenings for convenience. Some of the residents taking basic science training who demonstrate special aptitude, preparation and interest desire to become candidates for the degree of doctor of medical science; however, only those appointed in one of the affiliated hospitals or those who have completed a satisfactory residency and wish to spend not less than one year in one of the medical sciences are eligible for registration for the degree.

Several of the hospital services at Columbia have been reorganized as an expression of the changing needs of graduate training. The surgical service of the Presbyterian Hospital, for example, has been placed entirely on a graduate basis, the surgical internship being eliminated and a mixed medical service of eighteen months being made a prerequisite for the surgical residency. Similar changes have been made at St. Luke's Hospital and are being contemplated at other affiliated institutions. In his report for the year ended last June 30, Dean Willard C. Rappleye anticipates that as modifications in the house staffs of these affiliated institutions are effected, in keeping with the current trend toward a rounded educational experience for their residents, the facilities for graduate training at the medical school will be further utilized.

The Ten Highest in Part I

Among the 1,047 candidates who took the examinations of the National Board of Medical Examiners in June in Part I or completed Part I by taking subjects previously postponed, the names of those who made the ten highest average grades, as reported in the *Diplomate*, are as follows:

NAME	MEDICAL SCHOOL	AVERAGE
Bertram Selverstone.....	Harvard '41.....	91.50
William G. Armstrong.....	Albany '41.....	90.50
George James.....	Yale '41.....	90.17
Robert W. Raymond.....	Albany '41.....	90.17
Ernest M. Hammes.....	Harvard '41.....	90.
Edward O'Connell.....	Yale '41.....	89.67
Craig W. Borden.....	Harvard '41.....	89.
H. W. Diefendorf.....	Yale '41.....	89.
Sheldon C. Sommers.....	Harvard '41.....	89.
Sidney Cramer.....	New York Med. College '41.....	88.83

The Ten Highest in Part II

Among the 224 candidates who took the examination of the National Board of Medical Examiners in June in part II, the names of those who made the ten highest average grades are as follows:

NAME	MEDICAL SCHOOL	AVERAGE
Frank H. Russ.....	McGill '39.....	88.40
Phyllis J. Burdon.....	Oregon '39.....	87.40
Lester M. Narins.....	Long Island '39.....	87.20
Debora Pineles.....	Medical College of Virginia '39..	86.40
Robert M. Smith.....	Harvard '38.....	86.20
William B. Stromme.....	Minnesota '40.....	85.80
Aaron Kellner.....	Chicago '39.....	85.60
Sam J. Merenda.....	St. Louis '39.....	85.40
Edmund J. Schmidt.....	Marquette '40.....	85.20
William G. Marcoux.....	Tufts '39.....	84.80

Students Invited to Clinical Meeting

Medical students in New Orleans were especially invited to attend a joint meeting of the New Orleans Gynecological and Obstetrical Society and the Mercy Hospital staff at Mercy Hospital December 6. The speakers were Drs. Max M. Green on infection of the upper urinary tract; Philips J. Carter on urethral caruncle; Rupert E. Arnell, Chicago, on granuloma venereum of the cervix, and William F. Guerriero, Monroe, La., on criteria for the management of toxemia of pregnancy.

Fees at Arkansas

According to the official announcement of the sixty-first annual session of the University of Arkansas School of Medicine, Little Rock, the total tuition and annual deposit fees for residents and nonresidents are \$275 and \$430, respectively, for each of the four year courses. There is also a diploma fee of \$10. This total does not include the breakage fee, which is fixed by each department. The building fee, which is included in these totals, was increased to \$75 for residents and \$80 for nonresidents, but this increase is not applicable to students who registered prior to 1937-1938. Students who fail to register and fail to pay fees on the dates named are required to pay \$5 additional. Students have the privilege of using an available locker by paying at the registrar's office \$1 rental. A fee of \$5 is to be paid at the time of registration by each student for the Student Activities Fund.

Orientation Lectures for Freshmen

The University of Georgia School of Medicine, Augusta, inaugurated this year a series of orientation lectures for the freshman class. The following lectures were given in this series: The Importance of the Humanities by Dr. George L. Kelly, dean; Philosophy in Every Day Life by Dr. Eugene E. Murphey, professor of clinical medicine; Heredity and Medicine by Dr. Joseph Krafka Jr., professor of microscopic anatomy; Ethics in Daily Life by Dr. Virgil P. Sydenstricker, professor of medicine; Environment and Adaptation by Dr. Hervey M. Cleckley, professor of psychiatry, and Science and Knowledge by Dr. Fred A. Mettler, professor of anatomy.

Prizes Awarded at Woman's Medical College

At the recent eighty-seventh annual commencement of the Woman's Medical College of Pennsylvania, Philadelphia, Isabel Roberts Roe received the John Stewart Rodman Prize for the member of the graduating class who made the best record in surgery; Isabella M. Schmitz-Dumont, the Anna Howard Shaw Prize of \$20 for her thesis "Prevention of Anesthetic Deaths"; Rita E. Scott, the Sarah Marchand Milligan Book Award for her thesis "Effect of Occupation on the Cardiovascular System"; Dorothy O. Dart, the Martha Tracy Book Award for her thesis "The World-Wide Problem of Malaria Control," and Barbara Harris, the Dr. Hubley R. Owen Prize for the best examination in junior surgery.

Oklahoma Personal

Jay E. McCormick, a graduate of the University of Oklahoma School of Medicine, Oklahoma City, gave a talk on his experiences in medical school at the annual banquet of Alpha Epsilon Delta honorary pre-medical fraternity at the University of Oklahoma.

The Charity Hospital Intern Corps

About 150 new junior interns at the Charity Hospital, New Orleans, representing medical schools throughout the United States, held a meeting to outline a program of activities for the year. The Junior Club Committee is obtaining speakers for a series of addresses to the interns. Another committee has prepared a short summary of majority opinion among the interns and presented it to the resident staff in an effort to round out the curriculum during the intern year. Dr. Richard Ellis Gardner has been elected president of the intern corps, and Dr. Jerome A. Weaver, secretary. The corps was addressed the evening of October 10 by Dr. Urban Maes, professor of surgery at the Louisiana State University Medical Center, New Orleans, on intestinal obstruction.

Recreation Room for Students

Washington University School of Medicine, St. Louis, has furnished, for the first time, a recreation room for students on the second floor of the Osear Johnson Institute. The room is furnished with comfortable chairs, card tables and a book shelf, and nearby are rest rooms and facilities for ping pong; the medical students are also permitted to use the handball and squash courts when they are not occupied by the interns at Barnes Hospital. These courts, on another floor, have showers and lockers available.

Scholarship at the University of Kansas

The Porter Scholarship is awarded to the student at the University of Kansas School of Medicine, Kansas City, who has the highest average class standing for the first three years. It is given in the fourth year and amounts to \$300.

Prizes Awarded Students at Jefferson

The following prizes were awarded by the dean, Dr. Henry K. Mohler, at the commencement of Jefferson Medical College of Philadelphia, June 2, 1939:

The Henry M. Phillips Prize of \$75 awarded on the recommendation of the professor of medicine to the graduate most worthy, to Fred S. Badman, with honorable mention of Furman Payne Covington.

The Henry M. Phillips Prize of \$75 awarded on the recommendation of the professors of surgery to the graduate, in their opinion, most worthy, to Louis Harry Schinfeld, with honorable mention of George Lewis Greaser.

A gold medal awarded for the best essay on a subject pertaining to the practice of medicine, to George Hollander.

A gold medal for the best essay on a subject pertaining to surgery, to Isadore Slovin.

By Professor Anspaeh, \$25 for the best examination and clinical report on gynecology, to Arnold Valenzuela Arms, with honorable mention of Isadore Slovin, Paul Fried and George Hollander.

By Professor Williams, \$25 for the best examination in ology, to Charles Hugh O'Donnell, with honorable mention of James Thomas Grimes.

A gold medal for general excellence in clinical surgery, in memory of Francis Torrens Stewart, to George Beverly Hood, with honorable mention of James Edward Cochran and John Joseph Barrett Kilker.

By Professor Vaux, \$25 for the best examination in obstetrics, to James Joseph Fitzpatrick, with honorable mention of George Beverly Hood and Arthur Robert Wertheim.

By Professor Rugh, \$25 to the member of the senior class presenting the best report of the clinics in orthopedic surgery, to William Joseph Wagner, with honorable mention of Paul Fried and Louis Harry Schinfeld.

By Professor Bauer, \$25 for the best examination in pediatrics, to George William Miller III.

By Professor Shannon, \$25 for the best examination in ophthalmology, to Joseph Medoff, with honorable mention of David Dennis Dunn and Daniel Geddie Monroe.

By Professor Clerf, \$25 for general excellence in laryngology and bronchoscopy, to Henry Herbert Stroud.

By Professor Alpers, \$25 for the best examination in neurology, to Henry Herbert Stroud.

By Clinical Professor Keyes, \$25 for the best examination in psychiatry, to Jack Ralph Wennersten.

A gold medal for the best examination in therapeutics, to Henry Herbert Stroud.

W. B. Saunders Company Prize. Seventy-five dollars' worth of their medical publications to the student who passes the best general examination at the end of the senior year, to John Dominick DePersio.

William Potter Memorial Prize, awarded to that graduate attaining the highest general average in the final two years of the medical course, to Henry Herbert Stroud.

By the Alumni Association, a medal for the best general average gained in the examinations for the entire curriculum, to Arthur Robert Wertheim.

Physiology Prize, a gold medal for the best essay, or the best examination, on a subject pertaining to physiology (open to undergraduates of the second year), to Charles Michael Gruber Jr.

A gold medal, awarded to the student who has the highest grade in the anatomic subjects of the freshman and sophomore years, to John Young Templeton III, with honorable mention of Frederick Balthas Wagner Jr. and Oliver Judson Kregar Jr.

D. Appleton-Century Company Prize. Fifty dollars' worth of their medical publications to the student who passes the best general examination at the end of the junior year, to Alan Murray Schaeffer.

Schaeffer Anatomic League Prize, a gold medal awarded to the member of the league presenting the best thesis in anatomy, to Frederick Balthas Wagner Jr., with honorable mention to George Francis Callett.

Aid for Students at University of Virginia

The University of Virginia Department of Medicine at Charlottesville maintains a personnel office for the benefit of students who wish to obtain employment. A new student should not attempt to attend the school unless he has resources to defray at least half of the expenses of the first session. Assurance of employment cannot be given until after the student's arrival at school. The university also has certain loan funds from which deserving students may obtain loans. There are also special scholarships open to medical students. The William A. Herndon Scholarships are awarded by the faculty after a competitive examination held during the summer. These scholarships carry a stipend of about \$500 and continue for four years of the medical course and are awarded to candidates unable to pay for their medical education who signify their intention of entering the medical services of the army or navy of the United States. Two appointments will be made in September 1942. The Richard Henry Whitehead Scholarships are awarded to promising male students who have finished at least two years of the medical course. New appointments to these three scholarships will be made for the session of 1939-1940. The two Henry Clay Marchant Scholarships with a stipend of \$360 each under certain stipulated conditions may be awarded to medical students who are preparing to be medical missionaries.

The stipend of the State Scholarships is the remission of \$100 of the tuition fee. The tenure is one year, but an incumbent may be reappointed each year for four years. The number of these scholarships awarded in any department in any year does not exceed 20 per cent of the enrolment of the undergraduate students from Virginia in any department in the preceding year.

In Honor of the Freshmen

The sophomore class at Temple University School of Medicine, Philadelphia, was host December 15 to the other classes at the annual dance given in honor of the freshmen, held in the auditorium of Mitten Hall. On this occasion, the freshmen were given the traditional medical school keys as favors.

Special Courses for Residents

The resident physicians at Charity Hospital, Touro Infirmary and the Eye, Ear, Nose and Throat Hospital, New Orleans, will have an opportunity for postgraduate study in ophthalmology in a two year course of seven months each, which opened Oct. 9, 1939. The course has been provided by both Tulane University of Louisiana School of Medicine and the Louisiana State University School of Medicine and is preparatory for the American Board of Ophthalmology. The didactic course has been divided into the following twelve sections, each of which will be given ten hours: (1) embryology and anatomy, (2) histopathology and the eye and orbit, (3) physiology of vision, psychology of vision, and physiologic optics, (4) refractions, (5) ocular motility, (6) external diseases of the eye, (7) ocular therapeutics, (8) ophthalmoscopy, (9) medical ophthalmology and clinical pathology, (10) neuro-ophthalmology and perimetry, (11) ophthalmic surgery: demonstration of cataract operation on cats' eyes, (12) diagnosis-examinations.

Indiana Personal

Dale E. York, of Bloomington, and Elbert Harold Laws, of Milan, seniors in the Indiana University School of Medicine, Indianapolis, have been appointed to internships in the Philadelphia General Hospital,

Philadelphia, in a competition with 150 applicants for thirty-five internships; they were two of six accepted from schools other than the University of Pennsylvania School of Medicine. The rotating internships will begin July 1, 1940.

Scholarships and Loans at Alabama

Among the prizes available to students at the University of Alabama School of Medicine, University, is the Phi Beta Pi medical fraternity annual scholarship of \$90, awarded each year to a worthy freshman matriculated by June 1. The award is made by a committee of professors to a man or woman who is in need of financial aid and whose previous scholastic record and other qualifications give promise of a successful career in medicine. The dean's prize, consisting of a set of Harvey Cushing's "Life of Sir William Osler," is awarded annually to a sophomore who in the opinion of the teachers of the sophomore class "gives promise of becoming the highest type of practitioner of medicine." The Joseph Henry Walker III Memorial Award of \$25 is given annually to a native Alabama student who after completing the first year gives promise of the most useful service in medical practice. This award is decided on by the senior teachers of the freshman class.

Prizes Available at Yale

Following are some of the prizes awarded to students at the Yale University School of Medicine, New Haven, Conn.:

The Campbell Gold Medal. Awarded to the student who secures the highest rank in the examinations of the course of diseases of women and children.

The Ferris Prize in Anatomy. Awarded to a first year student in the school of medicine who, in the opinion of the staff of the department of anatomy, merits recognition for the excellence of his work in dissection.

The Keese Prize. Awarded annually to the student who presents the best thesis.

The Parker Prize. Awarded annually to the graduating student who, during his course, has shown the best qualifications for a successful practitioner, the faculty to be the judges.

The Perkins Scholarship Prize. Awarded annually to the student making the best record in scholarship in the basic subjects of the medical and

The Ramsay Memorial Prize. Awarded annually to the student who has completed his first year in the department of clinical medicine.

Expenses at Alabama

For payment of fees at the University of Alabama School of Medicine the school year is divided into three fiscal terms, while for instruction the year is divided into two semesters. The tuition per fiscal term is \$30, the university fee per fiscal term \$16, the Student Activities Fee per fiscal term \$4.50, the laboratory fee per semester \$60 and the breakage and clinical deposit per semester \$20. The university fee covers registration, library, gymnasium, medical and incidental fees. The Student Activities Fee permits student membership in the athletic association and free admission to all intercollegiate contests on the campus in which the university team is one of the contestants and covers the subscription to the *Crimson-White*.

Students who are delinquent in paying their fees are required to pay a small additional sum. If the delay exceeds nine days a delinquent fee of \$5 is charged and, in addition, the president is required to cause the withdrawal of the student from the university unless a satisfactory explanation is given.

Table board for men varies from \$18.50 a month, if paid in advance, to \$25 a month with private families. Rooms in the quadrangle cost about \$6 a month, in Gorgas Hall \$7.50 and in the new dormitories, if two men occupy one room, from \$24 to \$30 a term, and with private families from \$7 to \$15.

Harvard Graduates' Internships

Following are a few of the graduates of the 1939 class of Harvard Medical School, Boston, who are serving internships at hospitals outside of New England: Dr. William M. McGaughey is serving a one year rotating internship at Mercy Hospital, Chicago; Dr. Joseph H. Phillips is serving a surgical internship at the Royal Victoria Hospital, Montreal; Dr. John F. Roach is serving a rotating internship in the United States Naval Hospital, Philadelphia; Dr. John A. Sims, a rotating internship at the Denver General Hospital, Denver, and Dr. Ernest H. Wood Jr. a rotating internship at the Philadelphia General Hospital, Philadelphia.

Scholarships and Fellowships at the University of Chicago

Seventy or more regular university fellowships are provided in all departments of the University of Chicago by appropriations from the general funds of the university. The university requires of holders of these fellowships a modicum of service to be done under the direction of the department in which the appointments are made. Such service may consist of assistance in reading and preparing examination papers, work on a university journal, or assistance in one of the departmental laboratories, libraries or museums; in no case is a fellow expected to devote so much time as to interfere seriously with his own particular studies.

In addition, there are several special and annual fellowships for advanced study in special fields. These appointments are made by the departments in which these honors are assigned and are usually to persons who have begun resident study. Among these fellowships are the Frank Billings Memorial Fellowship; the James B. Herrick Fellowship in Medicine; the Ernest E. Irons Fellowship in Medicine; the Wilber E. Post Fellowship in Medicine; the E. R. LeCount Fellowship in Pathology; the William H. Wilder Jr. Fellowship in Neurology; the Arno B. Luckhart Fellowship in Physiology; the Nicholas Senn Fellowship in Surgery; the E. Fletcher Ingals Jr. Fellowship in Laryngology and Otolaryngology; the Sydney Walker III Endowed Scholarship in Physiology, and various others. The Douglas Smith Foundation supplies funds to support various research projects in medicine, the fellowships awarded varying with the problems under investigation and the qualifications of the applicants. There are other scholarships available as well as special research funds and foundations, and endowed scholarships, information concerning which may be had on writing to the dean of students in the Division of Biological Sciences, Cobb Lecture Hall, room 216, University of Chicago.

Loan Funds at the University of Chicago

The University of Chicago publishes a special circular entitled "Awards and Aids," which gives details concerning all forms of aid to students and the routine methods of application for aid. This circular will be sent on request. Friends of the university have created loan funds to aid temporarily students of worth and promise. These funds are limited and are exhausted early in the academic year. There is also the Clara M. Coit Loan Fund for Medical Students, established to aid needy students who give promise of unusual service in medicine. Interest is charged at the rate of 4 per cent. Application should be made to the Dean of Medical Students. The Medical Students' Loan Fund, established by the Physicians Association of Cook County, is available for medical students, preferably Negroes, and is lent with interest at 4 per cent. Application should be made to the Dean of

Medical Students. The national fraternity, Alpha Epsilon Iota, has available a loan fund contributed by its members in memory of one of its members, Jane Darling Stevenson. The loans are restricted to women medical students in advanced classes. Further information about this fund may be obtained from the chairman of the national committee, Monica Donovan, M.D., 450 Sutter Street, San Francisco.

Michigan Personal

Among the new interns in the department of internal medicine at the University Hospital at Ann Arbor are Malcolm Block, William H. Bates and Sim P. Dimitroff, all of whom received their M.D. degrees from the University of Michigan School of Medicine, Ann Arbor, last June.

Expenses at North Carolina

The tuition and other fees for each quarter at the University of North Carolina School of Medicine, Chapel Hill, are (1) tuition and matriculation, \$88.34, including the fee for physical education, the library, infirmary service, debates, registration costs and membership in the athletic association; (2) student publications, \$2.30; (3) laundry deposit, \$8.50, and (4) student union fee, \$1, making a total for each quarter of \$100.14. Each student whose bona fide residence in North Carolina has not been established must pay an extra fee of \$33.34 for each fall, winter or spring quarter. Each student must provide himself with his own microscope. A deposit of \$10 is required for the first registration of the year to cover the cost of the materials purchased from the medical storeroom, and the balance left at the end of the college year will be refunded.

Board without room can be obtained in town for from \$22.50 to \$35 a month. The University Dining Hall Cafeteria serves food at such prices as will only meet necessary expenses.

Room rent in the university dormitories, including light, heat and service, ranges from \$5.50 to \$15 a month for each occupant. There is a new dormitory within a block of the medical building. All rooms are completely furnished, but students will provide their own pillows, bed linen for single beds, blankets and towels.

Wisconsin State Board Questions

The following questions in pediatrics were given at the examination held in Milwaukee, June 27-30, 1939, by the Wisconsin State Board of Medical Examiners:

(Answer six.)

1. Describe rubella:
 - (a) Give cause and diagnosis.
 - (b) Describe the five stages.
 - (c) What are its principal complications?
2. (a) Describe pertussis. Give cause, diagnosis; describe the various stages and treatment.
 - (b) Describe scarlet fever. Give diagnosis, cause, complications and treatment.
3. Differentiate between lobar and bronchial pneumonia in children, as to the onset and temperature curve. Give the prognosis and termination of the disease.
4. (a) Mention the important points in prevention and treatment of gonorrhea of the eye in infants.
 - (b) 1. Give the clinical features in the treatment of diphtheria.
 2. What preventive measures are recommended in transmission of the disease?
5. (a) Differentiate between scarlatina, measles and roseola.
 - (b) Differentiate between cerebrospinal meningitis and tuberculous meningitis in children.
6. (a) What are the symptoms of pyloric stenosis?
 - (b) Outline treatment and diet.
7. Describe the clinical, laboratory and x-ray findings of active rickets in infancy. Also treatment.

RECENT ADVANCES IN THE MEDICAL TREATMENT OF PERIPHERAL VASCULAR DISEASES

EDGAR V. ALLEN, M.D.

ROCHESTER, MINN.

Essential hypertension is a serious disease in the United States, accounting for perhaps twice as many deaths as cancer.¹ This condition has been entirely too much neglected by the medical profession for several reasons, which follow:

1. There is a belief that elevation of the blood pressure is a symptom and not a disease. What difference does it make, however, whether hypertension is a symptom or a disease, since it kills people who would survive if they did not have hypertension? Failure to treat hypertension because "it is a symptom and not a disease" is entirely illogical and represents an attitude of mind which should be strongly condemned. There is need for reduction of blood pressure in essential hypertension.

2. There is a common belief that elevation of the blood pressure in essential hypertension is necessary for normal function of the body, particularly of the kidneys, and that reduction of blood pressure might seriously impair normal activity. There is no support for this belief. Our studies at the Mayo Clinic, and those of others, indicate that blood pressure may be reduced by sympathectomy with the result that cardiac and renal function are improved, or, at least that they are not impaired. Almost uniformly, patients having hypertension feel better when their blood pressure is reduced by operation than they felt before its reduction. Headache, dizziness, pain in the thorax and nervousness are benefited in a routine way when the blood pressure is reduced. Dyspnea and fatigue with exertion may occur after operation but tend to disappear as the time after operation increases. None is disabled.

3. There is an attitude of hopelessness concerning the treatment of essential hypertension. Many physicians have tried remedy after remedy highly recommended in advertisements and by detail men but have failed to demonstrate any beneficial effects of these preparations on blood pressure. Pessimism is justified in many instances but the situation does not appear to be hopeless.

The mechanism by which blood pressure is elevated is well known. The arterioles offer increased resistance to the flow of blood through them. In the earlier phase

of most instances of essential hypertension, this increased resistance is functional and reversible as is shown by the observation that rest, sedatives and anesthetics reduce the blood pressure to normal or nearly to normal. All that is needed to lower blood pressure in early phases of essential hypertension is a drug which produces prolonged vasodilatation but no harmful side effects. Preferably the drug should be effective when taken orally, but that is relatively unimportant. A drug with such an action is not now available, as far as I know. However, probably it can be made. Studies are in progress now.

Unfortunately, there is not much new to report in the medical treatment of essential hypertension but I shall briefly discuss the use of potassium thiocyanate, which is not new but has been much better controlled in recent years. Barker² has shown that the blood pressure of about 50 per cent of hypertensive patients is reduced by careful treatment with potassium thiocyanate. The amount of this drug which is administered should be determined by frequent calculations of the concentration of cyanate in the blood, which ordinarily should range between 8 and 12 mg. per hundred cubic centimeters. The technic has been described by Barker and has been modified by Griffith and Lindauer.³ As little as 3 grains (0.2 Gm.) and as much as 12 grains (0.8 Gm.) of potassium thiocyanate must be administered orally each day to cause this concentration in the blood. Such symptoms as headache, insomnia and nervousness may be relieved whether or not blood pressure is reduced. Fatigue, microcytic anemia and enlargement of the thyroid gland may occur even if administration of the drug is well controlled. If concentration in the blood is too great, lethargy, mental confusion, weakness, difficulty of speech, cutaneous lesions and collapse may occur.

THROMBOPHLEBITIS, VENOUS INSUFFICIENCY, VARICOSE ULCER

There is not much essentially new in the treatment of thrombophlebitis but there has been wider recognition of the pathologic changes occurring in this disease and of the physiologic disturbances which result from it. Thrombophlebitis should be considered an episode of acute inflammation of a vein, resulting in thrombosis. It is improbable that there is ever chronic phlebitis, although phlebitis may appear recurrently. Treatment after the acute phase consists, therefore, of prevention

From the Division of Medicine, the Mayo Clinic.
Read before the New York Academy of Medicine, New York, May 4, 1939.

1. This is an estimate. Reliable statistics on this subject are not available.

of venous stasis which may result and of prevention of recurrent episodes of phlebitis. Acute superficial phlebitis occurring spontaneously or in varices should be treated simply by rest and application of hot moist packs until there is no further extension of inflammation and until local signs of inflammation have disappeared. This is usually from seven to ten days. Sometimes roentgen therapy or the use of sulfanilamide hurries disappearance of inflammation. Prevention of recurrence of idiopathic phlebitis is largely unsatisfactory. Sometimes removal of foci of infection and cessation of smoking seem to help. In other instances, vaccines made from organisms cultured from the nasopharynx, prostate gland, teeth or tonsils seem to cause diminution in the number of episodes or of disappearance of them.

In the treatment of femoral and iliac thrombophlebitis one must consider (1) the possibility of pulmonary embolism, (2) management during the acute stage of the disease and (3) the prevention of chronic venous insufficiency of the limb. Once the signs and symptoms of femoral and iliac thrombophlebitis appear, the danger of pulmonary embolism is comparatively small. In their statistical study of 116 consecutive cases of fatal, postoperative, pulmonary embolism, Barker and Counseller⁴ found that thrombophlebitis of the femoral and iliac veins which could be recognized clinically was present in only five cases. Conversely, in a series of fifty-four cases of postoperative femoral and iliac thrombophlebitis fatal pulmonary embolism occurred only once and small, nonfatal pulmonary emboli occurred in only three other cases. The danger of pulmonary embolism in clinically recognizable, postoperative femoral and iliac thrombophlebitis, therefore, usually seems to be dependent on a new episode of thrombosis in a different vein.

The treatment which Barker and Counseller have used during the acute stage of iliac and femoral thrombophlebitis is comparatively simple and consists of adequate elevation of the leg (to an angle of 30 degrees from the horizontal) obtained by using a back rest covered with pillows. Hot wet packs are applied continuously from the foot to the groin. Elevation of the leg and local application of heat are continued until the patient's temperature has remained normal for four days, until all swelling and edema have disappeared from the leg below the knee and until all pain and tenderness have disappeared from Scarpa's triangle and the region of the large veins distal to it. This usually requires from ten to eighteen days. We feel that it is not necessary to keep the patient in bed for a longer time and that prolonged periods of rest in bed favor rather than prevent the development of other episodes of thrombosis and embolism. Prolonged rest in bed also favors the development of atrophy of the muscles of the leg, osteoporosis and postphlebotic neurosis, which has been described by Allen and Brown.⁵

It is necessary to equip the patient with an adequate support for the affected leg as soon as he gets out of bed and to instruct him to use it consistently for a period of months. In the presence of partial venous obstruction, marked increase in venous pressure is likely to be responsible for the rapid development of chronic venous insufficiency, recurrent static edema, secondary varicose veins and subsequently even chronic cellulitis and ulceration of the skin. The manifestations

of chronic venous insufficiency rarely, if ever, occur in the thigh. Hence it is not necessary to apply the support above the knee; furthermore, this is difficult and not practicable. It is necessary that the support prevent edema when the patient is standing and walking and that it be comfortable. Several types of support have been used. In cases of femoral and iliac thrombophlebitis the cloth and rubber are usually inadequate. Heavy elastic stockings may be adequate if they are made to measure and if they fit well. They have the disadvantages of being expensive, of wearing out or losing their elasticity in a few months and of not being adjustable. The most satisfactory support is a heavy, pure rubber bandage applied over a cotton stocking from the toes to the knee, with only a small portion of the heel exposed. The shoe should completely overlap the lower margins of the bandage. The advantages of this rubber bandage are that it will prevent orthostatic edema in practically all cases, that it can be adjusted until it is comfortable and that it is relatively inexpensive and does not wear out for a long time. Its disadvantages are that it is hot, particularly in the summer, that some patients, particularly women, object to its appearance as compared with that of an elastic stocking and that some skins are abnormally sensitive to rubber. The bandage or elastic stocking should be worn all the time that the patient is up and around. Each month the patient should go without the bandage for one day. Whenever edema does not occur, the support can be discarded.

The literature contains reports of several other measures which have been used in the treatment of thrombophlebitis during the acute state; namely, roentgen therapy, diuresis, application of leeches, dietary limitations and administration of sodium thiosulfate. Barker and Counseller have expressed the belief that results have not been any better in cases of postoperative thrombophlebitis when these measures have been used than when treatment consisted simply of adequate elevation of the limb, adequate application of moist heat to the limb, a comparatively short period of rest in bed and subsequently an adequate support for the leg. Leriche⁶ expressed the opinion that thrombosis itself in thrombophlebitis does not cause the symptoms which are actually due to venospasm and arteriospasm, the former of which is responsible occasionally for discoloration of the limb and the latter of which causes pain and offers obstruction to the flow of blood.

Recently a good deal has been written and spoken about the treatment of deep phlebitis by anesthetization of the lumbar sympathetic nerve trunks because it seems desirable to relieve impaired arterial circulation, which apparently results from phlebitis. I wish to make three comments: 1. It has not been demonstrated that impaired arterial circulation adds to the disability resulting from acute phlebitis. 2. It has not been demonstrated that relief of arterial spasm hurries convalescence from acute phlebitis. 3. If it is desirable to relieve arterial spasm, anesthetization of the lumbar sympathetic nerves is almost the most unsatisfactory method because it is complicated and the results are of short duration. Application of hot packs to the involved limb is probably as satisfactory and much simpler. Other effective ways of inducing vasodilatation are immersion of a hand in water at 113 F., diathermy, environmental temperature of about 85 F. and direct

application of heat to the body. I see no need for anesthetization of lumbar sympathetic nerves in acute phlebitis.

Nothing need be said here about the efficacy of the injection treatment of varicose veins; it is an accepted and usually successful method of treatment. Most interesting is the report of Duryee and Wright,⁷ who stated that iontophoresis with a 0.5 per cent solution of acetyl-beta-methylcholine chloride (mecholy) two to three times a week, for from six to 165 treatments, caused healing in nine cases of chronic varicose ulcer in spite of continuance of normal activity by all their patients. Kovacs⁸ had pointed out previously that iontophoresis was a way to secure a better local effect of the mecholy.

RAYNAUD'S DISEASE

Kraetzer⁹ expressed the belief that Raynaud's disease may be due to chronic intoxication from arsenic. The urine of seven patients who had Raynaud's disease contained arsenic.¹⁰ All were treated twice a week with intravenous injections of 0.5 Gm. of freshly prepared sodium thiosulfate for as long as twenty-two months or for as short a period as one month. Cure and marked improvement were noted. Kovacs, Saylor and Wright¹¹ reported that iontophoresis with mecholy in solution, given from two to three times a week, caused increased warmth of and improved color of the hands and feet and lessening of frequency with which attacks of discoloration occurred in twelve instances of Raynaud's disease. Both of these methods should be tried extensively, particularly in cases of Raynaud's disease not cured by sympathectomy.

ARTERIAL EMBOLISM

It seems clear now that diminution of circulation occurring when an embolism lodges in an artery is due only partially to mechanical obstruction by the clot. More important is the diffuse regional arterial spasm which results and which greatly impairs circulation (McKechnie and Allen¹²). If this spasm can be relieved promptly, circulation can be restored to a fairly normal state without removing the embolus. Relief of spasm in the limb can be accomplished in some instances by intermittent suction and pressure, intermittent venous obstruction, anesthetization of sympathetic nerves, spinal or general anesthesia, increased environmental temperature, induction of fever and by other means. Certainly such relief often occurs spontaneously. Papaverine hydrochloride, which is an anti-spasmodic, vasodilating drug, may help greatly if injected intravenously or into the artery above the site of the embolus (Allen and MacLean¹³). Papaverine hydrochloride when given intravenously may benefit

greatly the patient who has acute pulmonary embolism. Leriche, Fontaine and Friedman¹⁴ expressed the belief that anesthetization of the stellate sympathetic ganglion may help by relieving spasm of pulmonary arteries in this condition. Unfortunately their reported results were not impressive. Patients who have cerebral thrombosis may perhaps be benefited by the same procedure or by injecting papaverine into the carotid artery. It should always be borne in mind that in cases of arterial embolism and of sudden arterial thrombosis the chief therapeutic indication is to cause vasodilatation to relieve the regional arterial spasm commonly resulting from sudden arterial occlusion. Collins¹⁵ reported that fifteen of seventeen patients who had severe, massive, postoperative pulmonary embolism recovered following the use of papaverine. Six of seven patients who had embolism of the arteries of the extremities recovered. It is to be hoped that others have as good results as Collins has had. Our results are not nearly as impressive as those of Collins but I do believe there is some merit in this type of treatment. Papaverine hydrochloride one-half grain (0.032 Gm.) is about the right amount to inject intravenously or intra-arterially. More can be given with caution. Injections can be repeated every hour or so, depending on the reaction of the patient.

THROMBO-ANGIITIS OBLITERANS

Cessation of Smoking.—Hardly new, but well worth emphasizing again, is the great importance of complete cessation of smoking by patients having thrombo-angiitis obliterans. It is well known that tobacco smoking causes impairment of arterial circulation, manifested in the extremities by decreased cutaneous temperature, in the general condition by increased blood pressure and in the eyes by visible arterial constriction. These changes in circulation are, to be sure, transient but, when a patient smokes heavily, impairment of circulation may be persistent during hours in which the patient smokes. Abnormal arterial and arteriolar constriction is far removed pathologically from organic arterial changes, yet there is evidence that prolonged spasm such as that induced by ergot may produce organic changes in arteries. Friedlander, Silbert and Laskey¹⁶ have shown that an extract of commercially denicotinized cigarettes in Ringer's solution, injected intraperitoneally into male albino rats, may cause gangrene of the toes. One of the six rats subjected daily to inhalation of tobacco smoke for five months was afflicted with gangrene of the toes and one of ten animals treated by daily intraperitoneal injections of alkaloid nicotine tartrate also developed gangrene. Furthermore, Helmer, Kohlstaedt and Page¹⁷ have shown that the blood and urine of tobacco smokers may contain rather large amounts of nicotine, which may produce organic changes in some way as yet not understood. More important than any of these considerations, however, is the often repeated clinical observation that patients having thrombo-angiitis obliterans who continue to smoke do not ordinarily improve as much as do patients who cease smoking. It is difficult to impress on patients the importance of stopping smoking.

To do so I tell them "You can have your legs or your tobacco but not both." Subsequently I qualify the statement.

Intravenous Injection of Typhoid Vaccine.—In several clinics the repeated intravenous injection of typhoid vaccine to induce fever and to effect vasodilatation has been the most successful method of treatment of thrombo-angiitis obliterans. In a report of 150 cases in which treatment was administered by this method, Barker¹⁸ wrote that in 86 per cent pain while the patients were at rest was relieved if ulceration was absent, healing of ulcers occurred in 86 per cent, and healing of gangrene limited to the toes in 65 per cent. In 76 per cent of all cases repeated intravenous injections of typhoid vaccine to induce fever caused marked improvement. Barker pointed out that definite vasodilatation in the extremities could be demonstrated and that relief of pain was of a greater degree than could be explained by induced vasodilatation. This method of treatment has the advantage of simplicity and cheapness. It requires no machinery, which is perhaps one reason why it does not appeal more strongly to physicians or patients. I consider it the best of all methods of treatment in many cases of thrombo-angiitis obliterans.

Sulfanilamide.—Administration of this drug has proved useful in treatment of the acute or subacute infections so often associated with ulcerated or gangrenous lesions of thrombo-angiitis obliterans, and in treatment of acute phlebitis. Patients who have thrombo-angiitis obliterans who are under close observation should be treated with sulfanilamide or neoprontosil given regularly or intermittently over long periods. There is excellent opportunity for such a study to determine whether thrombo-angiitis obliterans is due to infection which can be minimized or eliminated by sulfanilamide.

Sodium Iodide Thiosulfate.—This drug has been recommended by Rabinowitz,¹⁹ because in his opinion it palliates the deleterious effects of anoxemia by increasing absorption of oxygen by the tissues, lengthens coagulation time, diminishes the tendency to thrombosis and converts choline into nontoxic compounds. Rabinowitz gave 50 grains (3.3 Gm.) of sodium iodide thiosulfate intravenously every other day for three weeks and twice a week thereafter for two months. All foods rich in phospholipins were eliminated from the diet. As a result of this treatment, pain disappeared and healing of gangrenous lesions occurred in sixty-three cases of thrombo-angiitis obliterans. As yet I have not seen reports by others of similar results, and we at the clinic have not benefited patients in a limited trial of treatment with sodium iodide thiosulfate.

A Proprietary Pancreatic Preparation (padutin).—Loeweneck and Madlener²⁰ gave slow intravenous infusions, over a period of from eight to ten hours, of 40 to 80 units of padutin in from 1 to 2 liters of physiologic solution of sodium chloride and repeated the injection every few days. Between periods of slow intravenous infusion, single injections of the preparation were given. The investigators noted relief of pain, improvement in arterial pulsations, increased warmth of skin and improvement in ulceration in thrombo-angiitis obliterans. This method of treatment should be given further trial.

ARTERIOSCLEROSIS

Frequently the concentration of fats in the blood is definitely increased. A quick conclusion is that the arterial changes are due to the increased concentration of fats or that the two result from a common cause. Leary²¹ has maintained that atherosclerosis results directly from impaired metabolism of cholesterol. Huber, Broun and Casey²² have shown that atherosclerosis, easily induced in rabbits by feeding cholesterol, can be prevented by administration of a pancreatic extract (lipocaic) which also prevents increase in the concentration of cholesterol in the blood. The pancreas may have another hormone in addition to insulin which is specific for metabolism of fat and this hormone may be perverted in quality or diminished in quantity in some cases of arteriosclerosis obliterans, producing both hyperlipemia and atherosclerosis. Perhaps ingestion of too much fat and cholesterol is responsible. Much can be expected from researches in this field in the near future. Leary quoted Shields and White to the effect that reduction of fat and cholesterol in the diet of diabetic patients reduces the incidence of atherosclerosis to normal and that a similar arrangement of diet causes xanthomas and roentgenologic evidence of arteriosclerosis to disappear. There is no close agreement on this matter. It is certain that elimination of sources of animal fats, that is eggs, milk and its products, and fat meats, from the diet has reduced greatly the concentration of the fats in the blood in many instances of hyperlipemia. It is worth trial in all cases in which the quantity of fats in the blood is increased.

COMMON METHODS OF TREATMENT OF BOTH ARTERIOSCLEROSIS OBLITERANS AND THROMBO-ANGIITIS OBLITERANS

The Sanders Bed.—Barker and Roth² have studied the results of treatment of eighty-eight patients having chronic occlusive arterial diseases by means of the oscillating Sanders bed. The results may be summarized as follows:

1. Relief of simple rest pain: Twelve of thirteen patients were completely relieved during treatment. Eleven of thirteen patients were permanently relieved by treatment.²³

2. Relief of pain of ischemic neuritis: Nine of fifteen patients were completely relieved during treatment. All fifteen patients were relieved by continued treatment.

3. Relief of pain associated with ulcers and gangrene: Thirty-two of forty-four patients were completely relieved during treatment. Twenty-two of forty-four patients were permanently relieved by treatment.²⁴ Healing occurred for all these patients.

Of thirty-four patients who were relieved during treatment on the Sanders bed, twenty-one were either not relieved or their pain was made worse by intermittent suction and pressure. Three patients were relieved by passive vascular exercise and not by treatment on the Sanders bed, while nine patients were relieved of pain equally by the two measures and eight were relieved by neither form of treatment.

The principle of treatment by the Sanders bed is that of passive postural exercises which allow intermittent filling and emptying of capillaries, venules and probably of arterioles. There is not much conclusive objective evidence that the circulation is improved, although the cutaneous temperature and oscillometric index may be increased.

23. Six patients had other treatment.
24. Ten had other treatment.

Intermittent Venous Compression.—Reports of value differ greatly, varying from those indicating that the method has no value whatever to those indicating remarkable improvement in the status of patients who have chronic occlusive arterial diseases. By using either a specially constructed machine or an ordinary blood pressure cuff manually, the limb is compressed for two minutes and then the pressure is released for two minutes. Patients who have open lesions are treated continuously day and night, and the cuff is inflated to from 30 to 40 mm. of mercury. After three days, treatment is reduced to from eight to ten hours daily. Patients who have no open lesions are treated continuously, pressures as high as from 60 to 80 mm. of mercury being used. Compression and release alternate for several hours daily. The treatment is based on the observation that hyperemia follows release of venous compression. There is some (but inconclusive) evidence of increased blood flow. The supporters of the method believe that treatment carried out for many hours produces persistent increases in circulation in contrast to the transient hyperemia which follows simple release of venous compression.

Collens, Wilensky and Ginsberg²⁵ reported the healing of 71 per cent of patients having gangrene and ulceration due to thrombo-angiitis obliterans, and relief of pain in 85 per cent of cases. Better results occurred in the treatment of nondiabetic patients having arteriosclerosis obliterans, but the results were less good in the treatment of diabetic patients having arteriosclerosis obliterans. Seven patients who had acute embolus and arterial thrombosis were relieved of pain, four recovered completely, two died but did not require amputation, and one patient required amputation. De Takats²⁶ reported that coldness and numbness of the extremities are relieved first, that intermittent claudication is influenced little and slowly and that "rest pain, if present, is a sign of serious circulatory disturbance and at this stage little can be expected from such treatments." He differed, therefore, with Collens and Wilensky, who reported marked relief of rest pain. Some physicians who have used intermittent venous occlusion adequately say that it has no value as a therapeutic method. I have had inadequate experience with it, but I doubt that the method has much virtue.

Kountz and Smith²⁷ used five cuffs to increase the venous pressure. The pressure was usually 40 mm. of mercury in the most proximal cuff and about 20 mm. of mercury in the other cuffs. The system is inflated and deflated about every six minutes for two hours a day. Improvement was noted in the condition of patients having thrombo-angiitis obliterans and arteriosclerosis obliterans, but unfortunately for dispassionate evaluation of the method of treatment several other forms of treatment were administered simultaneously.

Intermittent Arterial Compression.—Thiele²⁸ described a method of compressing the arteries to an extremity by means of an ordinary sphygmomanometer. The pressure in the cuff is maintained above the

systolic blood pressure for five, ten or fifteen minute periods and is then rapidly deflated for ten or fifteen minutes before reinflation. According to Thiele, such manipulation causes hyperemia. The cycle of inflation-deflation is repeated from five to eight times during one course of treatment.

Theoretically, according to Thiele, during the stage of compression the blood flows into the veins, the vessels collapse, metabolic changes occur and the blood vessels dilate. At the beginning of treatment little or delayed rubor occurs when the cuff is deflated and moves distalward slowly. After some treatment the reactionary rubor occurs promptly and intensively and quickly involves the entire extremity. Thiele reports relief of pain and restoration of circulation in two cases of arteriosclerosis obliterans and in other cases in which the diagnoses were vascular spasm with hypertension, angiospasm and dyspraxia angiospastica. Interestingly, patients having chronic arthritis were greatly benefited. The method is worthy of more extensive trial. It is perhaps a sign of unwarranted skepticism that causes one to doubt that the results will be as good as indicated by Thiele.

Diathermy.—Bennett²⁹ and others have emphasized the effectiveness of short wave diathermy in producing peripheral vasodilatation. Application is made to the lumbar region by means of a cable or by applying one pad to the lumbar region and the other to the lower portion of the abdomen or to a thigh. In the presence of chronic occlusive arterial diseases the cutaneous temperature begins to increase in about fifteen to twenty minutes and reaches a maximum in, roughly, a similar period of time. When diathermy is discontinued, the cutaneous temperature of the toes of a patient clad with only a sheet decreases in about forty-five minutes to that value which had obtained before institution of the treatment. If the patient is wrapped in blankets, peripheral vasodilatation may persist for several hours, since the oral temperature increases as much as 3 degrees F. (approximately 2 degrees C.) and this fever persists for some time, provoking peripheral vasodilatation. Extensive observations have not yet been made on the relief of pain and clinical improvement. It is unfortunate that the vasodilatation induced by short wave diathermy persists so briefly, but it is no more illogical to assume that permanent vasodilatation may result from this form of treatment than it is to assume that permanent vasodilatation may result from intermittent venous or arterial compression or from intermittent suction and pressure. Diathermy has a contrasting advantage over many other forms of treatment in that it obviously produces an increase in the flow of blood.

Administration of Sodium Chloride by Mouth and Intravenously.—Sandstead and Beams³⁰ noted that the oral administration of sodium chloride causes relief of pain caused by neuritis and impaired circulation in the presence of diabetes, and definite signs of improvement in circulation, such as healing of gangrenous ulcers and indolent ulcers, and improvement in the color and temperature of the feet. These authors gave from 15 to 90 Gm. of sodium chloride daily over periods of ten to fourteen days, with interruptions of ten to fourteen days. They felt that the beneficial effects were the result of vasodilatation induced by the ingestion of

salt, although they showed no evidence of such an effect. Silbert³¹ advised repeated intravenous injections of hypertonic solutions of sodium chloride for patients having thrombo-angiitis obliterans. An initial injection of 150 cc. of a solution of 5 per cent sodium chloride is administered and all subsequent injections are 300 cc. of a 5 per cent solution, given at the rate of about 30 cc. per minute. At first injections are given on alternate days, later twice a week, and still less frequently as improvement occurs. Treatment is continued for from six weeks to two years. As a result of this method of treatment, to which were added occasional nerve section for relief of pain, and cessation of smoking, the incidence of amputation was decreased from 62 per cent to 6.4 per cent. Silbert believes that thrombo-angiitis obliterans is not a progressive disease when patients stop smoking. Samuels³² has confirmed Silbert's observations relative to the beneficial effects of a repeatedly injected solution of 5 per cent sodium chloride. Although some observers are not enthusiastic about the treatment outlined by Silbert and by Samuels and are frankly skeptical of the therapeutic results, it is apparent that patients receiving this treatment from these two investigators have improved remarkably. As in many other situations, it is difficult to determine whether or not the improvement was due to this treatment alone.

The Administration of Sodium Citrate Orally or Intravenously.—Bernheim and London³³ reemphasize the value of administration of sodium citrate, of which 250 cc. of a 2 per cent solution is administered intravenously as often as daily for as long as six months but on an average of only three months. It may be administered orally also. When cessation of smoking, a diet high in calcium and vitamins, avoidance of worry, and diminished physical activity were added to this method of treatment of fifty-four patients having thrombo-angiitis obliterans and ninety-nine patients having arteriosclerosis obliterans, excellent results followed. Intermittent claudication was benefited in about 75 per cent of cases, rest pain was relieved in about 80 per cent of cases and ulcers were improved in about 85 per cent of cases. These authors believed that the administration of sodium citrate reduced viscosity and fibrinogen of the blood and increased the excretion of calcium. If I read their charts correctly, all five patients having thrombo-angiitis obliterans were improved by dietary treatment alone, as were thirty of thirty-one patients who had arteriosclerosis obliterans. One wishes that Drs. Bernheim and London had studied a group of patients for whom even a diet was not prescribed. Would the results have been as good?

Intermittent Suction and Pressure.—This method of treatment has been much favored since it was redescribed by Herrmann³⁴ and by Landis and Gibbon³⁵ in 1933. Herrmann devised the machine which is now used commonly for the improvement of circulation in occlusive arterial diseases by intermittently decreasing and increasing the environmental pressure around the extremities. He believed that pressure should be equivalent to about 20 mm. of mercury and that it should endure for about three seconds, while suction

should be equivalent to about 80 mm. of mercury and endure about twelve seconds. The treatment is intended to dilate collateral arterial pathways and thus improve circulation. Herrmann reported the recovery of six of seven patients who had arterial embolism, all of fourteen patients who had acute arterial thrombosis, improvement of intermittent claudication in many instances, relief of pain and healing of gangrenous ulcers in twenty of twenty-one patients who had advanced thrombo-angiitis obliterans, and much improvement in the condition of patients who had arteriosclerosis obliterans. Excellent results in treating such patients were reported in previous publications. Unfortunately the method of classification of occlusive vascular diseases as presented in Herrmann's monograph is so unorthodox and the presentation of results of therapy is so indefinite that the reader cannot evaluate results of treatment for himself. Various other students of peripheral vascular disease have not agreed that Herrmann's ingenious method of treatment is of first class therapeutic benefit.

Kountz and Smith,³⁷ for example, found that definite improvement followed treatment of only one of seventeen patients who had arteriosclerosis obliterans, and very minor improvement of only two of eight patients who had thrombo-angiitis obliterans. There were no notable changes in the oscillometric index, and injections of colloidal thorium dioxide showed no improvement in the collateral circulation. Brown and I⁵ did not find intermittent suction and pressure method of treatment of much clinical value. Wilson and Roome³⁶ reported twelve cases of arteriosclerosis obliterans with subjective improvement in five instances but no permanent objective evidence of improvement. Of eight patients who had thrombo-angiitis obliterans, six were not benefited; intermittent claudication was improved in two instances.

Holman³⁷ modified the boot devised by Herrmann so that it could be applied directly to the thigh. The pressure within the chamber alternates every five seconds from —70 to +50 mm. of mercury. Holman believed that such a chamber exerted its influence on undiseased vessels instead of on occluded arteries, as the passive vascular exercise boot does, and he pointed out that it could be used in the presence of infection and when pain made the boot intolerable. Holman felt that the thigh chamber was actually a peripheral heart which draws blood into the extremity during the phase of suction and which forces blood into the peripheral arteries during the phase of pressure. I doubt that this opinion can be supported by physiologic evidence. He wrote that the clinical results obtained from treatment with the suction pressure chamber applied to the thigh were better than those obtained with passive vascular exercise. Too few results have been presented to allow evaluation of the method by the reader.

SUMMARY DISCUSSION OF METHODS OF TREATMENT OF CHRONIC OCCLUSIVE ARTERIAL DISEASES

When one reads of the results of various methods of treatment for chronic occlusive arterial diseases, two things are impressive. The reported results are surprisingly good and the reported results of one particular method of treatment duplicate surprisingly the reported

37. Holman, Emile: Recognition and Treatment of Peripheral Vascular Occlusion, Northwest Med. 37: 65-71 (March) 1938.

results of other methods of treatment. This correlation can be explained in several ways. Perhaps the results are as good as reported because of specific methods of treatment and perhaps the surprising correlation of good results of individual methods of treatment is due to the fact that only a certain percentage of patients can be benefited. Perhaps also there is too much enthusiasm on the part of the investigator who reports good results either because he has a definite pride in the method which he has originated or because he is not sufficiently experienced to exercise cautious judgment. This would appear to be definitely true when other students cannot confirm the good results of a specific method of treatment. Perhaps the specific method of treatment is not responsible at all for improvement or, if it is, it is responsible only remotely, while most benefit originates from good general care such as cessation of smoking, rest in bed, warmth and comfort.

The number of reported cures for chronic occlusive arterial diseases indicates that the field of vascular diseases has come of age. It is now almost on a par with gastro-enterology, for example, since there are, similarly, many "cures" for duodenal ulcer. It is well to emphasize that almost all the good reports of treatment of thrombo-angiitis obliterans are based on clinical results, a shaky foundation at best when numerous factors must be considered. There is surprisingly little objective evidence to support the conclusion that much of the treatment causes a definite increase in the flow of blood to extremities deprived of blood. Even if an individual treatment causes increased circulation transiently, one cannot conclude that repeated treatments cause a permanent increase in circulation unless there is definite objective evidence that this is true.

That which has been said in the foregoing paragraphs is relatively unimportant. Much more important is the fact that progress is being made in treatment, even if by chance it is not as great as some reports indicate. There is still much to be accomplished, for Horton³⁸ has shown that many patients receive little or no treatment and that, of these, about 60 per cent will require amputation within ten years' time. It is only when this percentage is greatly reduced that we of the medical profession can have much pride in our treatment of chronic occlusive arterial diseases.

Food, Fun and Frolic.—Apart from disease of the central nervous system and grave physical defects, the prevailing notions as to the relation of mens sana and corpus sanum have been grossly exaggerated. Malnutrition, poverty, dirt, and even a succession of acute or chronic diseases do not seem able of themselves to subdue the master organ of the body, the brain, to any considerable extent. On the other hand it is obvious that malnutrition, poverty, dirt, disease and war do wipe out individuals, families and races. The effect on the race or the breed should not be confused with the effect on the brain of the individual. The psychological effects of class gymnastics have not been considered any more than the psychological effects of grooming, dress and personal adornment. The present problem is anatomical and physiological. Growth, development, posture, like health, depend to a large extent on the freedom for the individual to join in any play, game or sport, to exert himself according to his powers, and to know when he has had enough. Food, fun and frolic are of more importance than drill and discipline. —Harris, H. A.: The Anatomical and Physiological Basis of Physical Training, *Brit. M. J.*, Nov. 11, 1939.

CHICAGO

Many problems concerning the human requirement for vitamin A could be solved if a reliable measure of subclinical vitamin A deficiency were found. The biophotometer test has been suggested for this purpose, but work in this as well as in other laboratories has shown that the test is only fairly reliable and that its relation to stores of vitamin A has yet to be demonstrated. A review of the literature suggests that determinations of vitamin A in the blood may offer another approach to this problem. The present study was consequently undertaken. It includes the results of chemical determinations of vitamin A and of carotene in the blood, as well as biophotometer tests, of five subjects over periods of from two to four months. During this period four of the subjects lived on vitamin A depletion diets save for two short periods of supplementation; the fifth served as the control. Single determinations were also made of the vitamin A and carotene in the blood of thirty-four adults in order to have some idea of the range of values found in normal subjects. Our purpose in this study, as already indicated, was to determine whether the level of vitamin A in the blood is closely related to the body's stores of this vitamin.

LITERATURE

During the last few years a number of studies on the vitamin A and carotene content of human blood have appeared in the literature. With the exception of the work of Clausen and his associates¹ these studies have all been done in foreign countries. The material as a whole is quite heterogeneous in nature as it includes subjects of all ages, races and classes and in various states of health. Furthermore, there is no uniformity in the methods used by the various investigators. Several modifications of the antimony trichloride method for determining vitamin A have been made and the vitamin A equivalents of the "blue units" reported vary with the modification used; the absolute values reported by the various laboratories, therefore, are not strictly comparable. Few of the reports mention whether or not fasting blood was used and in no case are there any quantitative data as to the nature of the diets of the subjects. For these reasons the results of most of the studies are not pertinent to the present problem and will therefore not be reviewed here. Since, however, the extent of the studies and certain of their general conclusions are of interest, they are summarized in table 1.

It will be noted that these studies present but little direct evidence as to whether or not the vitamin A in

From the Department of Home Economics, the University of Chicago. Helen Parkes took all the blood samples and Drs. Clausen and McCoord helped the authors with the method.

the blood is related to the body's stores, although several of the authors assume that such a relationship exists. Certain indirect evidence on which there is general agreement make this assumption seem logical: 1. Subjects suffering from a definite vitamin A deficiency have little or no vitamin A in their blood. 2. Subjects from low socio-economic groups, whom one would expect to have poor stores, have on the average less vitamin A in their blood than subjects from the higher socio-economic groups. It is obvious, however, that the significance of these observations cannot be settled until more controlled studies have been made in which the vitamin A and carotene are determined on the fasting blood of normal subjects on a known intake of vitamin

and vitamin A. These four experimental subjects were college students. They were in good physical health and with fair or good dietary histories. There was no doubt, however, that subject G. S. had been receiving the most vitamin A, since several months previously she had taken large amounts of vitamin A concentrate. Subject E. S., on the other hand, had probably been receiving slightly less vitamin A than the other subjects, since her diet included few dairy products or eggs. The one control subject used for this portion of the study was also a college student with a good dietary background.

The thirty-four subjects from whom single samples of blood were obtained were volunteers, either university students or employees. While an attempt was

A supplement increased the vitamin A more or less rapidly
Clausen, S. W., and McCoord, A. B.: The Carotenoids and Vitamin A of the Blood, <i>J. Pediat.</i> 13 : 635-650 (Nov.) 1938	Over 1,400 subjects mostly children; various pathologic conditions	(1) Individual determinations vary greatly; (2) the rate of absorption of vitamin A is slower than that for carotene; (3) infection causes a decrease in vitamin A and carotene; (4) when the carotene intake is diminished the blood level falls slowly

A over a long enough period to determine the expected variation. The present study was undertaken as a contribution to this problem.

METHOD

The general plan of the study, as previously stated, was to place a group of subjects on a diet as low as possible in vitamin A and to note the effect of such a diet, with and without small supplements, on the blood level of vitamin A and carotene and on the biophotometer readings. To support these data single samples of blood were taken from thirty-four adults, half of whom had been receiving a supplement of vitamin A.

Subjects.—Four subjects were used to test the effect of a vitamin A low diet on the blood level of carotene

made to secure some idea of their dietary histories, the records were not quantitative and therefore were of little value in ascertaining the amount of vitamin A that these subjects had been consuming, except in the case of those who were taking concentrates. Thirty-one of these thirty-four subjects were given two or more biophotometer tests each.

Plan of the Experiment.—The experiment consisted of a long depletion period, 123 days, which was preceded and followed by a week of an adequate diet containing between 7,000 and 10,000 units of vitamin A daily. During the depletion period the subjects ate all their meals in the laboratory. While no assays were run, the diet as calculated averaged 67 units of vitamin A daily. All the food eaten, including the breads and cakes, was prepared in the laboratory. The diet was

weighed and each subject ate identical amounts of any food which contained vitamin A or carotene.

Three of the subjects continued on this vitamin A low diet for the entire period of more than four months, the fourth subject for fifty-two days. The three subjects each received six small supplements² of 1,000 units of vitamin A, the first on the sixty-fifth, the others on the seventy-second to the seventy-sixth days. The fourth subject, E. S., was given 2,000 units daily during her last week on the experiment.³

The blood samples for the study were taken in the morning before breakfast. Samples were taken twice a week from the four subjects on the depletion diet and once a week from the control subject. When supplements were being given, the blood was taken at least twenty hours after the supplement had been administered.

Each of the four subjects was tested daily on the biophotometer during the first seventy-two days of the study and at frequent intervals thereafter. The control subject was also given frequent biophotometer tests throughout the study.

Determination of Carotene and Vitamin A.—The method used for determining the vitamin A and carotenoids in the blood was that described by Clausen and McCoord.⁴ The essentials of the method are as follows:

Three cc. of serum or plasma is used for a determination. The proteins of the serum are precipitated by 95 per cent alcohol, which has been shown to help in releasing the vitamin A so that it can be more easily extracted. Three cc. of petroleum ether is used for extracting the vitamin A and the carotenoids. One cc. of this petroleum ether extract is used for the determination of the carotenoids and a second one for vitamin A.

In determining the carotenoids the petroleum ether is evaporated and equal portions of two immiscible solvents hexane and diacetone alcohol are added. The carotenoids present are thus separated into a "xanthophyll" and a "carotene" fraction because of their difference in solubility in these two solvents. The amount of carotenoid in each fraction is determined colori-

metrically against a 0.02 per cent potassium dichromate standard and the results are expressed as gamma of "carotene" and gamma of "xanthophyll" per hundred cubic centimeters of serum.

The vitamin A is determined by a modification of the Carr-Price antimony trichloride method. The blue color is read in a colorimeter against a 10 per cent copper sulfate standard. The blue units obtained are corrected for the carotene and xanthophyll present and are expressed as blue units⁵ of vitamin A per hundred cubic centimeters of serum.

It is recognized that small amounts of other carotenoids are probably in both the "carotene" and

Chart 1.—The amount of carotene and vitamin A in each sample of blood from each subject.

"xanthophyll" fractions and that the blue color produced with antimony trichloride is not due to vitamin A alone. The limitations of the method are discussed in publications from the Rochester laboratory and so will not be reviewed here.⁶ Suffice it to say that the major portion of the color in each instance is due to the substances under consideration; namely, carotene and vitamin A. Furthermore, the errors in the method are minimized in a study of this type, which consists chiefly of repeated determinations of the blood values of subjects on a constant diet, the only variable being an increase or decrease in the vitamin A supplement. No serious misinterpretations of the data should be involved if the values are treated not as absolute but as relative ones and if small changes are regarded as insignificant.

2. The supplement was given as U. S. P. reference cod liver oil.
3. It was necessary for E. S. to leave the city; hence the shorter length of time on the study.

RESULTS

Vitamin A and Carotene in the Blood.—As previously stated, samples of blood were taken from the four experimental subjects twice a week and from the control subject once a week throughout the study, thus making a total of thirty-six determinations for three subjects, twelve for the fourth and eleven for the control. The results of the determinations of both vitamin A and carotene are shown in chart 1.

Chart 2.—Biophotometer readings and vitamin A in the blood of each subject during the study.

It will be noted that the average amount of vitamin A in the fasting blood of the subjects at the beginning of the study ranged from 7.1 blue units for the lowest subject (E. S.) to 22.1 blue units for the highest (G. S.), and the carotene ranged from 60 to 85 micrograms per hundred cubic centimeters of serum. The original levels of vitamin A in the blood of these subjects fits in well with their dietary histories, at least as far as the extremes are concerned. Subject G. S., who had a history of large amounts of vitamin A supplement, showed the highest value and subject E. S., whose dietary history was slightly inferior to the others, the lowest. The blood levels of all the subjects were well within the

range of values found by Clausen in the blood of children, but three (11.0, 10.5 and 7.1 blue units) tended to be near the lower limit of the range, where he states the majority of his subjects fall; namely, between 10 and 20 blue units. Since, however, these determinations were all made on fasting blood, they might well be expected to be somewhat lower than those reported in the literature on nonfasting blood. It seems only logical to assume that a meal taken several hours before blood was drawn would affect the amount of vitamin A in the blood, since it has been shown that a supplement of vitamin A causes a maximum rise of as much as 900 per cent in four hours.⁷ The fact that these subjects were adults while most of Clausen's subjects were children may also account in part for the level of vitamin A and carotene tending to be low. While the subjects had fairly good diets, these diets were probably relatively lower in vitamin A than are those of the modern child. It will be shown later that subject E. S., who showed the lowest value (7.1 blue units), may have had suboptimal stores of vitamin A. In general, then, these data on the original levels of vitamin A in the blood of the subjects were in good agreement with their dietary histories and with values reported in the literature.

Another point of interest in chart 1 is the variability in the determinations of various samples of blood from the same individuals. This tendency for the level of vitamin A in the blood to vary has been mentioned by most workers in the field; its occurrence in a study of this type, in which the subjects were on a practically constant diet and only fasting blood was used, was unexpected. There was slightly greater variation between the amounts of both vitamin A and carotene in the blood from the control than in that from the experimental subjects. This is probably explained by the fact that her intake of vitamin A and carotene varied, while the experimental subjects were on a constant diet.

One of the most important observations in chart 1 is the marked fall in the vitamin A and carotene level of the blood caused by the depletion diet. The greatest decrease was noted in subject G. S., who had the highest original level (from 22.1 to 7.1 blue units), and the smallest in subject E. S., who had the lowest original level (from 7.1 to 5.0 blue units). A tendency is noted for the vitamin A in the blood of all the experimental subjects to approach that of the lowest subject; namely, 6.0 blue units per hundred cubic centimeters of serum. The values for the control subject varied from 11.5 to 18.9 blue units, with a mean of 15.5; but, as would be expected, there was no consistent tendency for them either to increase or to decrease throughout the study.

The effect of a supplement of vitamin A on the amount in the blood may be observed in this chart by noting the sections marked with arrows to designate when the supplement was given. It will be seen that, beginning with the forty-fifth day of the depletion diet, subject E. S. was given 2,000 units of vitamin A a day for seven days, while the other three subjects were given no supplement until the sixty-fifth day and then only a single 1,000 units capsule.² The supplement given E. S. caused a rapid rise in her blood level of vitamin A from an average of 6.0 blue units for the depletion period to 12.5 blue units, a value appreciably higher than that found in her blood during the preliminary period (7.1 blue units). The first supplement

7. Chesney and McCoord.¹

given to the other three experimental subjects was only 1,000 units, but even this small amount caused a decided rise in the vitamin A in the blood of all the subjects. This is of special interest in light of the fact that the supplement was taken twenty-three hours before the blood was drawn. After this one small supplement of vitamin A the amount in the fasting blood fell slowly and by the end of the week had reached its original low level. When the same small supplement of 1,000 units

TABLE 2.—The Range, Mean and Standard Deviation of the Determinations of the Vitamin A and Carotene in the Blood of Thirty-Four Adults, One Half of Whom Had Received a Supplement of Vitamin A

Classification of Subjects	Number of Subjects	Micrograms of Carotene per 100 Cc. of Serum			Blue Units of Vitamin A per 100 Cc. of Serum		
		Mean	Standard Deviation	Range	Mean	Standard Deviation	Range
Subjects who had taken no supplement.....	17	115	31.3	82-210	9.1	2.6	4.8-14.0
Subjects who had taken a supplement.....	17	130	41.9	58-250	15.8	3.0	11.7-20.8

was again given for two days, a greater increase in vitamin A in the blood occurred, and when given for three additional days a still higher level was attained. The amount of vitamin A in the blood of all the subjects was maintained at a high level for two weeks after the supplement was discontinued and then slowly fell.

Although the vitamin A low diet was continued for forty-two days after the supplement was stopped, in only one case did the vitamin A in the blood fall to as low a level as that in the first part of the study. In two subjects, S. B. and K. M., the rise in vitamin A in the blood caused by the supplement resulted in a higher level than that observed at the beginning of the study when the subjects were on a normal diet. The fact that the blood level rose so high and fell so slowly after a supplement of only 1,000 units of vitamin A a day is difficult to explain. These subjects, even with the addition of the supplement, were still getting much less vitamin A than during the preliminary period, following which the blood level had fallen rapidly. Furthermore, 1,000 units of vitamin A is less than the suggested minimum requirement for human beings.

The fact that in the ordinary mixed diet the major portion of vitamin A value is furnished by carotene may have some bearing on the problem. The amount of vitamin A per se in the preliminary diet, however, was probably well over 1,000 units, although it is impossible to calculate just how much of the total vitamin A value was in this form as assays of foods are done by the biologic method, which does not differentiate between carotene and vitamin A. The main animal sources of vitamin A in the preliminary diet were dairy products and eggs, both of which may vary greatly in their carotene content as well as total vitamin A value. There is, therefore, the possibility that the preliminary diet may have contained less vitamin A and more carotene than an inspection of it would indicate. The data, however, clearly show that even a small supplement of vitamin A caused an increase in the amount of this substance in the fasting blood of the subjects on a vitamin A low diet and that this increase was main-

tained for an appreciable length of time. Furthermore, the increase in blood value and the period the increase was maintained were both roughly proportional to the amount of supplement given.

The carotene values of the blood were apparently not affected by the supplement of vitamin A, as they became progressively lower throughout the study until an adequate diet was resumed. What little vitamin A the experimental diet contained was from vegetable sources, so that it is not surprising that the blood always showed a small amount of this pigment. The carotene in the blood of the control subject, however, increased during the study. This may have been due to the fact that the study was carried on during the spring and summer when more fruits and vegetables were in season, or that she unconsciously chose foods higher in carotene because she knew that she was serving as a control for the study.

The amount of vitamin A and carotene in the blood of the thirty-four subjects from whom single samples of blood were obtained are shown in table 2 and chart 3. These subjects consisted of two groups; one half of them had been taking a supplement of vitamin A for three weeks while the other half had no supplement. There was a significant difference in the amount of vitamin A in the blood of the subjects in the two groups, as is evidenced by the fact that the mean value for those taking the supplement was 15.8 blue units per hundred cubic centimeters of serum and the standard deviation 3.0 blue units, while the mean value for the other group was 9.1 blue units, the standard deviation 2.6 blue units. There was, however, some overlapping in the values for the two groups, as the range for the supplemented group was from 11.7 to 20.8 blue units, that for the unsupplemented group from 4.8 to 14.0 blue units. This is not surprising in view of the fact that the diet histories of some of the subjects in the unsupplemented group showed very generous amounts of vitamin A and carotene.

As might be expected, there was less difference in the mean values and range of values for carotene in the

Chart 3.—Scatter diagram of the biophotometer readings and vitamin A blood values of thirty-one adults.

two groups than for vitamin A. It is interesting, however, to note even a small difference in the mean carotene values for the supplemented and unsupplemented group, 130 versus 115 micrograms of carotene, since the supplement taken by the subjects was not carotene but a product containing vitamin A.

In summary, then, this study, which includes repeated determinations of the amount of vitamin A and carotene

in the fasting blood of subjects on a vitamin A low diet for a period of four months, shows the following:

1. The original level of vitamin A in the blood of the subjects was related to their dietary histories.
2. The blood values of vitamin A fell rapidly when the subjects were placed on a vitamin A low diet, although there was considerable variation noted between individual determinations.
3. Small supplements of vitamin A caused the amount of this substance in the blood to rise rapidly but had no effect on the carotene.
4. The vitamin A blood level reached after a supplement and the length of time that this level was maintained were both affected by the size of the supplement given.
5. The average amount of vitamin A in the fasting blood of subjects receiving a supplement of vitamin A was significantly higher than that of subjects who had no supplement.

Relation Between Vitamin A in the Blood and Biophotometer Readings.—Since it has been claimed that the biophotometer test is an index of a subject's nutritional status as regards vitamin A, it is interesting to compare the trend of the biophotometer readings and vitamin A in the blood of these subjects. The method followed in giving the biophotometer tests was that described by Jeans and his associates.⁸ Only the readings for the first test in the recovery period are reported here, as in every case these readings reflected the general trend of the test as a whole. Chart 2 shows the individual biophotometer readings, in dial spaces, for this point in the test and the amount of vitamin A in the blood of each subject plotted according to time.

Attention is directed first to the upper three charts, those of subjects G. S., S. B. and K. M. It will be noted that there is no relationship between the original biophotometer readings and the amount of vitamin A in the blood, nor is there any tendency for the two to parallel each other as the study progresses. Although the biophotometer tests vary from reading to reading, their general trend is surprisingly uniform. One cannot, in fact, tell from them when the subjects were receiving a supplement, when they were on a deficient diet or when they were on an adequate diet. In contrast to these the lower lines, which represent the blood values, show definite drops and rises coincident with the withdrawal or restoration of vitamin A to the diet. The trend of these is definitely affected by the amount of vitamin A in the diet.

In the fourth chart, that of subject E. S., it will be noted that the vitamin A low diet and subsequent supplement did have a decided effect on the biophotometer readings. The fact that this subject showed impaired dark adaptation after forty-five days on the depletion diet indicates that her stores of vitamin A may have been suboptimal. If this assumption is correct, her original low blood value of only 7.2 blue units of vitamin A per hundred cubic centimeters of serum might be considered as indicative of low stores; her original biophotometer readings, however, were the highest of any of the subjects and would therefore have to be considered of no diagnostic value.

Further comparisons of vitamin A in the blood and biophotometer readings can be made from data from thirty-one of the group of thirty-four subjects studied who were each given two or more biophotometer tests.

Chart 3 shows a scatter diagram in which the blood values of vitamin A and the biophotometer readings for these subjects are plotted. It will be noted that the data represented cover a wide range of values but that there is no tendency toward a correlation. It is clearly evident, therefore, that here, as in the case of the four subjects on the depletion diet, there is no relationship between biophotometer readings and the amount of vitamin A in the blood.

In a study reported elsewhere of the reliability and validity of the biophotometer test, of which this study was a part, we have shown that while there is no doubt some relationship between the biophotometer readings and the nutritional status of the subject with respect to vitamin A, the relationship is not close enough to make the test of use as a diagnostic measure. Therefore the lack of relationship between the biophotometer test and the blood values reported here furnishes no evidence as to whether the blood values are related to the vitamin A stores of an individual. It is evident, however, in the case of the five subjects studied most extensively, that the original blood values agree better with the dietary histories of the subjects than do their biophotometer readings and that the fasting blood level responds more quickly to changes in vitamin A intake than do the biophotometer readings.

COMMENT

From this study it is evident that the amount of vitamin A in fasting blood is directly affected by the amount in the diet. It is obvious, moreover, that the fasting blood level must reflect not only the diet of the preceding day but to some extent the habitual level of intake. This is shown by the following: 1. The original blood levels of the four subjects on the depletion study were in the same order as the amount of vitamin A they were in the habit of eating, as judged by their dietary histories, even though they had been on similar diets for a week previous to the time the blood was drawn. 2. The depletion diet caused a decrease in the amount of vitamin A in the blood of all the subjects, but an appreciable period of time elapsed before their blood values reached the same low level. 3. The subject with the lowest original blood value was the only one of the four for whom there was any evidence of impaired dark adaptation on the depletion diet. 4. A small supplement of vitamin A added to the depletion diet caused an immediate rise in the amount found in the fasting blood, but the withdrawal of the supplement did not cause an immediate fall. 5. The blood from the seventeen subjects who had been receiving a vitamin A supplement contained more vitamin A than that from the unsupplemented subjects. This interpretation of the blood values is also supported by the evidence from the literature, namely, that higher blood values were obtained in subjects from a high than from a low socioeconomic status, and subjects showing clinical symptoms of vitamin A deficiency as a rule had very low blood values.

The acceptance of this contention that the vitamin A in fasting blood is partially dependent on the amount eaten the previous day and partially on the past diet does not, however, answer the crucial question of whether or not blood studies can be used as a measure of nutritional status in respect to this vitamin. Several observations made in the present study make it clear that the blood level at any given time does not necessarily reflect the body's stores. This is illustrated in

8. Jeans, P. C.; Blanchard, Evelyn, and Zentmire, Zelma: *Dark Adaptation and Vitamin A*, J. A. M. A. 108: 451-458 (Feb. 6) 1937.

the case of G. S. For several months preceding the study she had been supplementing an already adequate diet with large amounts of vitamin A concentrates and her stores should theoretically have been filled. Nevertheless, when placed on the depletion diet, her blood level fell rapidly and at the end of two months was approximately the same as that of the other subjects. Thus her blood level at this point in the study would have indicated that her stores were no better than theirs, while actually they should have been far better.

The same lack of relation between blood level and theoretical vitamin A stores is shown by the response to the supplement. Following a total addition of only 6,000 units of vitamin A, or little more than a normal day's intake, the amount in the blood of three of the subjects rose above the original level and remained there for several days in spite of the fact that the subjects had been on a vitamin A deficient diet for from forty-five to sixty-five days, and their stores should presumably have been at least partially depleted.

Even though the blood levels of vitamin A cannot be relied on to reflect the stores when abrupt changes are made in the dietary, nevertheless the data from this study and those in the literature would indicate that the blood level for vitamin A of subjects on their usual diet, if observed over a reasonable period, might give some indication of the subject's reserves of this vitamin. It appears obvious that if fairly large amounts of vitamin A are consistently found in the blood of a subject (e. g., 16 blue units or more) there is little doubt that his diet, and consequently his stores, contain generous amounts. Conversely, if low amounts are consistently found (e. g., less than 6 blue units) it would probably indicate that the body stores of the vitamin were in the process of being depleted. The determination of the vitamin A in a single sample of even fasting blood from any one individual would have little significance in either case, as it might easily be affected by the intake of the previous day and might not be truly representative of the diet as a whole.

If the biophotometer had proved to be a more sensitive and reliable means of determining mild vitamin A deficiency, the data presented would have been easier to interpret. In that case one would have expected to find a positive relationship between the biophotometer readings and the blood studies, provided of course that they both were related to the nutritional status of the subjects. Since, however, the biophotometer was shown to be of little use except in the case of quite marked dysadaptation, it was of no help in this problem.

While the data presented help to clarify several of the problems involved in the interpretation of levels of vitamin A in the blood, further research is necessary before their significance in relation to nutritional status can be fully understood.

SUMMARY

Semiweekly determinations were made of the amount of vitamin A and carotene in the blood of four experimental and one control subject during a four months depletion study. The conclusions from these data were supported by those from single determinations of these constituents in the blood of thirty-four adults, one half of whom had received a supplement of vitamin A. Biophotometer readings were made of the subjects during the depletion diet and of thirty-one of the other subjects.

The results of the study show that the amount of vitamin A in the fasting blood is dependent on the

amount in the diet. While the evidence as to whether or not determinations of the vitamin A in the blood are of value in judging nutritional status is contradictory, the data show that consistently low fasting blood values indicate that probably the body stores of vitamin A are being depleted and very high values that the intake of vitamin A is adequate. The results further show that there is no correlation between the amount of vitamin A in the blood and the biophotometer readings.

HYPERPARATHYROIDISM AND PREGNANCY

CLIFFORD L. SPINGARN, M.D.

AND

SAMUEL H. GEIST, M.D.

NEW YORK

The concept of disease caused by increased function of parathyroid tissue has been firmly established since Mandl's¹ successful removal of a parathyroid adenoma for osteitis fibrosa cystica in 1925. During the past thirteen years, more than 150 well studied cases of hyperparathyroidism have been reported and much has been added to our knowledge of the disease. However, a review of the literature revealed only one report dealing with pregnancy in a patient with hyperparathyroidism.² It is our purpose in this communication to record such a case and to discuss the interesting problem that it presents.

REPORT OF CASE

History.—A woman aged 29, an American-born dancer, was admitted to Mount Sinai Hospital with chronic hyperparathyroidism on Sept. 19, 1938, in the fourth month of her first pregnancy. Her family history was negative. She was a seven months infant weighing 5 pounds (2,268 Gm.) at birth. Her early history was uneventful.

Her past history is a good example of the course of chronic hyperparathyroidism.³ She enjoyed good health until she was 19 (1928), when attacks of renal colic caused her to enter another hospital, where two calculi were removed from the right ureter. Two years later (1930) a cherry-sized mass, which had appeared during the preceding three months, was excised from the left maxilla. This was a giant cell tumor. Shortly afterward she passed a left ureteral calculus without operative intervention.

In 1931 she fractured the right humerus. X-ray films showed a bone cyst involving the head and neck of the humerus in addition to a fracture of the surgical neck. The rest of the skeleton was normal. In 1935, on her sixth admission to the same hospital, she presented a painless swelling of the left lower jaw. Except for occasional vague pains in the extremities she had been perfectly well and continued an active life as a dancer. Roentgenograms of the entire skeleton now revealed generalized osteitis fibrosa cystica. The blood calcium was high, the inorganic phosphorus low and the serum phosphatase elevated. These observations led to a thorough but unsuccessful exploration of the patient's neck for a parathyroid adenoma. The bone cyst in the left mandible was excised for cosmetic reasons. This resulted in a sizable defect, which was filled with a bone graft in June 1938. Pathologic examination of a piece of rib removed for the graft showed osteitis fibrosa cystica.

From the Gynecological Service of Dr. Samuel H. Geist and the Division of Laboratories of the Mount Sinai Hospital.

2. Bevere, L., and Sorrentino, B.: *Contributo allo studio dell'osteite fibrocistica generalizzata*, *Riforma med.* 48: 313-318 (Feb. 27) 1932.

3. The details of the past history were made available to us by Dr. William F. MacFae.

In June 1938 the patient became pregnant. Previously her menstrual periods had always been regular and normal in every respect. She continued to feel well until the onset of nausea and vomiting during the third month. At this time she began to have an aching pain in both heels. She consulted a physician, who sent her to the Mount Sinai Hospital to have the proper management of her pregnancy determined.

Examination.—On admission the patient was thin and appeared chronically ill. There were no gross deformities. The hair was thin and silky. The nails were brittle and ridged. The skin was clear and of normal texture. There were many well healed operative scars. The lower incisors were very loose. Several teeth were missing. The blood pressure was 110 systolic, 70 diastolic. The only other abnormalities were those of early pregnancy. The vaginal mucosa was cyanotic, the cervix was soft and nulliparous and the mobile uterus was enlarged to about 3½ months. Hegar's sign was positive.

Examination of the blood revealed hemoglobin 72 per cent, red blood cells 4,200,000, white blood cells 9,800, polymorphonuclear leukocytes 70 per cent, lymphocytes 26 per cent, monocytes 4 per cent. The urine was neutral to acid and cloudy, contained albumin, clumps of white blood cells, rare red blood cells and granular calcium phosphate casts⁴ on repeated examinations, had a specific gravity which varied from 1.012 to 1.024, and a concentration test (Fishberg) showed a maximum concentrating power of 1.024. A phenolsulfonphthalein test (following hysterotomy) showed 75 per cent excretion of the dye in two hours.

Results of the chemical analysis of the blood are given in the accompanying table.

Results of Chemical Analysis of the Blood

	During Pregnancy		After
	9/22/38	9/26/38	Hysterotomy 10/10/38
Urea nitrogen per 100 cc.....	8 mg.	7 mg.
Sugar per 100 cc.....	75 mg.
Calcium per 100 cc.....	11 mg.	11.9 mg.	14.4 mg.
Phosphorus per 100 cc.....	2.4 mg.	2.6 mg.	2.7 mg.
Phosphatase	90 King	64.5 King
	Armstrong units		Armstrong units
Total protein per 100 cc.....	3.1 Gm.	3.2 Gm.	5.0 Gm.

The following hormone assays were reported (courtesy of Dr. Robert T. Frank): Normal pregnancy test: six day specimen of urine (from September 22 to 27) showed a three day estrogen output of $\frac{6,000 \text{ international units combined}}{1,250 \text{ international units free}}$; second specimen for a three day period $\frac{11,750 \text{ international units combined}}{3,000 \text{ international units free}}$; blood estrogen 100 international units per liter; urine gonadotropic (III) reaction 2,000 rat units per liter; blood gonadotropic (III) reaction 3,000 rat units per liter.

The Hamilton-Highman test⁵ for abnormal amounts of parathyroid extract in the blood gave negative results.

Metabolic Data: On a neutral ash diet, containing approximately 100 mg. of calcium daily, the patient had a urinary excretion of 1,293 mg. of calcium for a three day period, an average of 431 mg. daily (normal, from 80 to 100 mg. per day).⁶ After abdominal hysterotomy the urinary calcium increased slightly to 465 mg. daily on the same diet. To simplify the balance studies the calcium in the stool was not determined, since in hyperparathyroidism without renal insufficiency only urinary excretion of calcium is excessive.⁷

Röntgenograms: The long bones showed diffuse decalcification. Both humeral heads were cystic (fig. 1). There were similar but less well defined changes in both tibias. The pelvis showed large lacunar areas in the innominate bones. There was a generalized decalcification of the pelvic bones with a coarsening of the trabecular structure (fig. 2). The lower ribs showed similar changes.

The skull showed a diffuse thickening of the bones of the calvarium, especially at the outer table. The bones of the skull had an irregular mottled appearance simulating the so-called cotton-wool picture (fig. 3). The mandibles showed cystic areas on both sides. There was a cyst in a recent bone graft.

A flat plate of the abdomen showed three small concretions, which may be renal calculi, within the contour of the left kidney. The kidneys were normal in size, shape and position. X-ray films of the chest showed no abnormality in the lungs. There was no mediastinal tumor.

Course.—During her stay in the hospital, the patient was symptom free and tolerated the test diets well. She lost about 1 pound (450 Gm.) during the first balance study. Eight days after admission, abdominal hysterotomy was performed for reasons discussed later. The patient was delivered of a well formed fourteen weeks fetus. The postoperative course was uneventful. The patient was afebrile except for a slight postoperative temperature rise to from 101 to 102 F. for two or three days. She was discharged three and one-half weeks after admission.

THE FETUS

The specimen was a well formed fetus measuring 15 cm. from crown to heel. The weight was 78 Gm. X-ray films showed normal osseous development for a twelve to sixteen week fetus.⁸ There was no evidence of metastatic calcification.

The bones were examined microscopically, with material fixed in solution of formaldehyde or in Zenker's fluid and stained with von Kossa solution or hematoxylin and eosin. Sections through the humerus revealed straight thin primary zones of calcification (cartilage-shaft junction) with an orderly arrangement of thin calcified cartilage cores covered with bone on the shaft side. The subepiphyseal zone was vascular and contained a fair number of osteoclasts. The diaphysis was well developed and was composed of anastomosing trabeculae separated by spaces containing blood-forming marrow. Everywhere trabeculae were covered by osteoblasts. The osteogenic layer of the periosteum consisted of an unbroken line of osteoblasts. There was no evidence of marrow fibrosis or excessive osteoclastic activity. Osteoblastic function seemed normal. Sections stained for calcium (without decalcification) showed no impairment of calcium deposition in formed bones. Sections of the radius, ulna, tibia and metacarpal revealed similar changes. The impression was that of normal developing bone.

The parathyroids were identified on serial sections of the organs of the neck. Three glands lay posteromedial to the thyroid and one within the substance of the thyroid. Each was a round compact structure composed of closely packed cells with clear, unstained cytoplasm and round vesicular nuclei. There was a slight tendency to form alveoli. The glands showed no evidence of fibrosis or hemorrhage. The impression was that of normal developing parathyroid tissue.⁹

COMMENT

This case satisfies the clinical and metabolic criteria of hyperparathyroidism discussed at length in many reviews.¹⁰ The onset with renal calculi, the gradual appearance of osteitis fibrosa cystica, the demonstra-

tion of an excessive urinary excretion of calcium as well as hypercalcemia, hypophosphatemia and elevated serum phosphatase afford ample proof of increased parathyroid activity. The failure to find abnormal parathyroid tissue at operation is not unusual, considering the variability in the number and location of the human parathyroids.¹¹ "A positive diagnosis is a challenge to the skill and patience of the surgeon, and when these have been exhausted in a fruitless search for an adenoma, the operator is privileged to say 'the tumor cannot be found' but not 'the tumor does not exist.'"¹²

The decision to terminate this pregnancy was determined largely by the presence of extensive fibrocystic disease of the maternal skeleton associated with a negative calcium balance. This indication of moderately severe hyperparathyroidism led to the conclusion that it would harm our patient if she continued to bear the added metabolic burden of gravidity. We regret that we were unable to extend the period of observation to study the combined effect of increasing fetal mineral requirements and excessive maternal parathyroid function on the course and outcome of pregnancy.

The continuance of pregnancy with the patient in positive calcium balance was believed inadvisable in view of the tendency for diets rich in calcium, phosphorus and vitamin D to accelerate the development of serious renal complications of hyperparathyroidism.¹³ Likewise, reexploration for a parathyroid tumor during pregnancy was not attempted because it was felt that, even if the offending agent was found, its removal would endanger both mother and fetus by precipitating severe tetany.¹⁴ Thus a brief consideration of the possible effects of coexisting hyperparathyroidism and pregnancy will serve to justify abortion as the logical therapeutic measure.

An essential feature of hyperparathyroidism is the excessive excretion of calcium and phosphorus. The loss of calcium occurs chiefly in the urine, except in a few instances in which marked renal insufficiency increases the fetal calcium. The steady loss is associated with a reduction of the mineral content of the skeleton and the development of bone changes. These vary from mild osteoporosis, difficult to detect by roentgenograms, to severe osteitis fibrosa cystica, depending probably on the duration and intensity of the abnormal endocrine stimulus. In advanced cases the normal rigidity of the skeleton is lost. Fractures and deformities are common and may produce marked disability.

The steady depletion of her mineral stores limits the capacity of the pregnant woman with hyperparathyroidism to deal successfully with the fetal demand for calcium and phosphorus. This demand is of considerable magnitude, since the average term fetus contains about 25 Gm. of calcium.¹⁵ It has been estimated that there is a steady rise in the fetal absorption of calcium from 50 mg. a day at three months to 450 mg. a day during the tenth lunar month.¹⁶ During normal pregnancy, provided the diet is adequate, maternal retention of calcium exceeds the daily fetal requirements, except at

the tenth month, when the fetal need is almost double the average maternal retention and calcium must be withdrawn from the maternal reserves.¹⁶ In many instances, possibly as a result of inadequate intake or defects in calcium metabolism, the maternal tissues are called on to supplement the dietary supply of minerals still further, as shown by the not uncommon appearance of clinical phenomena during pregnancy referable to the drain of calcium from the mother.¹⁷ Osteomalacia is a good example of the effect of extreme deprivation of calcium and phosphorus on the course of pregnancy.¹⁸ This disease, characterized by softening and deformity of the bones, is common during pregnancy and lactation among populations whose diets are deficient in calcium, phosphorus and vitamin D. Under these circumstances the skeleton of the pregnant woman is demineralized by the intra-uterine parasite, which is often stillborn with evidence of fetal rickets.¹⁹

The case of Bever and Sorrentino² illustrates the effect of repeated pregnancies on a woman with hyperparathyroidism:

A woman aged 32 began to suffer from stabbing pains in both feet during the eighth month of her tenth gravidity. This pregnancy terminated successfully. During her eleventh pregnancy, one year later, there was an exacerbation of these pains, which spread to the thighs and upper extremities. She could not walk or sit down without severe pains. At term she gave birth to a dead fetus. During the subsequent months she felt very weak and lethargic. Clubbing of the fingers appeared. She again became gravid within a year. From the onset she could not move without severe pain and was completely bedridden. During the seventh month she fractured the left humerus while turning in bed. During the eighth month she sustained fractures of the right humerus, femur and clavicle, with the production of marked deformities. X-ray examination during the eighth month showed marked decalcification of the bones, which contained many large loculated cysts. The blood calcium was from 13.8 to 14.6 mg. per hundred cubic centimeters; inorganic phosphorus was from 2.9 to 3.1 mg. A negative calcium balance amounting to 400 mg. a day was demonstrated. The patient refused operation for removal of parathyroid tissue and gave birth to a normal baby girl whose bones showed no abnormalities on x-ray examination. Despite a resemblance to osteomalacia, this case was apparently one of hyperparathyroidism in view of the results of the x-ray and chemical examinations.

From the preceding data it is reasonable to conclude that pregnancy increases the damage to a skeleton whose mineral reserves have been depleted and whose ability to retain bone-forming materials is impaired by excessive parathyroid activity.

That pregnancy may be an etiologic factor in some cases of hyperparathyroidism is an interesting possibility suggested by the case of Bever and Sorrentino. Similarly, in the following reports, pregnancy seemed to be associated either with the onset or with an increase in the severity of unrecognized chronic hyperparathyroidism:

CASE 1.²⁰—A married woman aged 49, with bilateral renal calculi and generalized osteitis fibrosa cystica, was seen in 1929, ten years after she had begun to suffer from polyuria and polydipsia. She had one miscarriage at three months in 1918 and gave birth to a stillborn child just before the first symptoms of her illness in 1919. There were five other children living and well. A parathyroid adenoma was removed.

CASE 2.²¹—A woman aged 42 was seized with severe abdominal pain radiating to the back during the sixth month of her ninth gravidity. This was followed by a spontaneous abortion (stillbirth). During the next two years she gradually diminished in height and suffered from pain in both legs and difficulty in locomotion. A diagnosis of hyperparathyroidism was made then and a parathyroid adenoma was removed from behind the left pole of the thyroid.

CASE 3.²²—A woman aged 36 began to have attacks of renal colic during her fourth and last pregnancy. For the next four years she suffered from recurrent renal colic. Studies showed renal stones, blood changes suggestive of hyperparathyroidism and a negative calcium balance. A chief cell adenoma was removed from behind the right lobe of the thyroid. The patient made an uneventful recovery.

CASE 4.²³—A woman aged 23 was studied because her 5 months suckling infant suffered from severe tetany refractory to treatment. Except for vague tiredness during the previous few years, she was asymptomatic. Her blood calcium was found to be 16.4 mg. per hundred cubic centimeters, phosphorus 2.5 mg., phosphatase elevated and urinary calcium increased. X-ray examination showed granular calcium deposits in both kidneys; there was a small cyst in the left pelvic bone and another in the right femur. A parathyroid adenoma was removed.

CASE 5.²⁴—A multipara aged 40 gave a history of onset of severe epigastric pain for the first time during her first pregnancy at the age of 30. This recurred two years later during her second pregnancy. Both pregnancies terminated successfully. During the next three years she suffered from epigastric pain radiating to the back. This led to an examination which disclosed a compression of the eleventh dorsal vertebra and the metabolic manifestations of hyperparathyroidism. Operation for removal of parathyroid adenoma was unsuccessful. Biopsy was positive for osteitis fibrosa cystica. Since operation the patient has lost weight, suffers from intractable pain and has decreased several inches in height.

Several points support the suggestive case material and perhaps indicate a mechanism to explain the possible relationship between pregnancy and hyperparathyroidism. The disease is three times more common in women, in whom it occurs with greatest frequency after the age of 40.²⁵ We are unaware of a satisfactory explanation of this sex incidence. It is likely that many cases of hyperparathyroidism go unrecognized for many years, since the diagnosis is often obscure in early and mild cases.²⁶ Such cases afford ample opportunity for aggravating factors to exert their effects. Finally there is some evidence for a physiologic increase in parathyroid activity in response to the demands of normal gestation. Hyperplasia and increased vascularity of the parathyroids during pregnancy have been observed.²⁷ Moreover, several workers state that they have demonstrated abnormally large amounts of parathyroid extract in the blood of pregnant women during the last trimester.²⁸ It has been suggested that this increase in parathyroid function occurs to counteract the tendency for the blood calcium to fall during the last months of pregnancy by

liberating calcium from bone trabeculae or other sites of recent calcium deposit.²⁹

Parathyroid hyperplasia is encountered in a variety of conditions. Enlargement of the glands has been observed in rickets,³⁰ osteomalacia,³¹ renal dwarfism,³² chronic nephritis³³ and metastatic carcinomatosis of the skeleton.³⁴ Hyperplasia of the glands has been produced in rats by partial ablation of renal tissue.³⁵ In most of these states there is some evidence of increased parathyroid function. Excessive amounts of parathyroid extract have been detected in the blood in cases of rickets³⁶ and of chronic nephritis³⁷ and in a case of renal dwarfism.³² In each of these instances the parathyroid hyperplasia is probably compensatory to furnish increased amounts of hormone in response to calcium deficiency or hyperphosphatemia.

There are a few indications that compensatory hyperplasia occasionally gives rise to phenomena attributable to chronic hyperparathyroidism. In some cases of long standing renal insufficiency with secondary parathyroid hyperplasia a disease picture is encountered which is difficult to distinguish from primary hyperparathyroidism with renal complications.³⁸ An increase in the calcium content of the residual renal tissue of partially nephrectomized rats has been cited as evidence that the parathyroid hyperplasia produced by this procedure acts in a manner similar to excessive amounts of parathyroid extract.³⁹ Moreover, a tendency toward the formation of localized, apparently semiautonomous centers of excessive growth has been noted in the hyperplastic parathyroids of patients with chronic nephritis.⁴⁰

It is interesting that the diffuse parathyroid hyperplasia of rickets has been held responsible for the "relatively high incidence of hyperfunctioning parathyroid adenomas in England and New England, where the likelihood of vitamin D deficiency is favored by the indoor life of the industrial population."²⁵ According to this theory the presence of cell rests in the hyperplastic glands of rachitic patients forms the anatomic basis of the formation of adenoma. While this concept may explain the regional distribution of the disease, it throws little light on the question of sex incidence. In view of suggestive clinical evidence and certain disease-producing potentialities of parathyroid hyperplasia it is conceivable that pregnancy, with the introduction of factors enhancing parathyroid activity, may lead to permanent changes in the glands which precipitate and increase the severity of chronic hyperparathyroidism.

The effect of hyperparathyroidism on the development of the fetus is worthy of careful study, since there are little accurate data on this point. Theoretically, two influences could produce fetal abnormality: (1) alterations in the availability of calcium and phosphorus for the formation of bone and (2) the direct action of the maternal parathyroid hormone on the embryonic tissues. Insufficient calcium and phosphorus, because of a mineral deficiency in the mother, would tend to impair the calcification of the fetal bones, producing a condition like fetal rickets in osteomalacia.¹⁰ On the other hand, should the fetus be capable of diverting the maternal mineral stream from the path of excretion characteristic of hyperparathyroidism, the increased availability of bone-forming minerals might lead to excessive calcification of the developing bones. It is

Fig. 1.—Cystic area in head of right humerus.

interesting that premature calcification of bone nuclei was detected in a 5 months old infant whose mother was found to be suffering from symptomless chronic hyperparathyroidism.²² Moreover, hypercalcemia was noted in the mother of an infant with osteopetrosis (marble bones),⁴¹ while osteosclerosis has been observed in fetuses whose mothers received excessive amounts of calcium, phosphorus and vitamin D during gestation.⁴² Whether abnormal activity of the maternal parathyroids is capable of affecting the fetus directly is unsettled. Some evidence suggests that the placenta is impermeable to parathyroid extract and that the fetus possesses considerable tolerance to a few large doses of this substance.⁴³ However, the occurrence of refractory infantile tetany in the case of Friderichsen suggested an inhibitory influence of excessive maternal parathyroid secretion on the functional development of the fetal parathyroid apparatus.²³ This possibility is compatible with the finding that newborn infants not infrequently show signs of parathyroid deficiency.⁴⁴ The production of bone disease in young animals by repeated injections of parathyroid extract shows that age alone offers slight protection against the pathologic effects of an excess of this substance in susceptible species.⁴⁵

In our case the failure to detect changes in the fourteen weeks fetus is inconclusive owing to the small fetal mineral requirements at this age and to the short period

of contact with the abnormal endocrine stimulus. The successful termination of pregnancy in the case of Bevere and Sorrentino² is a remarkable demonstration of parasitic embryonic growth and lends support to the idea that the placenta is impermeable to parathyroid extract. However, the outcome of the previous preg-

Fig. 2.—Appearance of pelvis, showing large cysts, decalcification and exaggeration of trabecular structure.

nancy, as well as the occurrence of fetal death in two of the cases previously cited, in which pregnancy and unrecognized hyperparathyroidism seem to have coexisted, is perhaps indicative of a significant infant mortality.

SUMMARY

In a case of chronic hyperparathyroidism complicated by pregnancy, the pregnancy was terminated because

Fig. 3.—Lateral view of skull, showing mottled appearance of bones with thickening of calvarium.

it was felt that these states would affect one another adversely with unfavorable results for mother and fetus. In view of the evidence for increased parathyroid function during pregnancy, the possibility is suggested that pregnancy may precipitate or aggravate hyperparathyroidism in some cases, thus accounting for the increased incidence of the disease in the female.

BRONCHIOGENIC CARCINOMA

A DIAGNOSTIC ENIGMA

EDWARD L. JENKINSON, M.D.

AND

ARTHUR F. HUNTER, M.D.

CHICAGO

The recent voluminous literature on bronchiogenic carcinoma calls for justification in the presentation of a small group of cases. It may be said, however, that the capacity for early recognition of this disease has not kept pace with the increasing realization of its importance as a common condition. The trend of opinion about pathologic entities, in the present scheme of things, is a curious mixture of diverging views, few of which are not empirical. The importance of certain phases of problems depends on the frequency of reiteration from authoritative sources. It is unfortunate that we do not live in a medical utopia where some central registering agency, demanding uniformity of data, could have available the totality of facts on proved cases of any one condition. Things being as they are, however, we wish to emphasize the pathologic, clinical and roentgenologic nonconformity of bronchiogenic carcinoma, and we base our paper on twenty-three cases. The role this form of malignant process plays in simulating other conditions, its role as an imitator, is perhaps its most characteristic feature. Like the devil, it can appear in any shape or form.

INCIDENCE

The early history is traced to Morgagni (1761), whom Adler¹ recognized as the first to identify primary cancer of the lung. Barron² stated that Boyle (1810) described phthisis cancreuse as one of his six varieties of phthisis. Adler,¹ who in 1912 compiled 374 cases, was probably the first to dispel the belief in the rarity of primary carcinoma of the lung.

Graham,³ Edwards,⁴ Christie⁵ and Jaffé⁶ placed the incidence of bronchiogenic carcinoma somewhere between 5 and 10 per cent in relation to all carcinoma. At the University of Toronto for the ten year period ended 1936 the lungs and bronchi proved the third commonest site for malignant epithelial tumors as seen at autopsy.⁷

Whether the increased incidence is apparent or real remains unsettled. Klotz⁷ stated that the strongest argument for belief in a real increase is to be found in reports coming from institutions which have been under the same supervision and have required the same standards of diagnosis for a number of years and that "an increase under such conditions has been reported by Rosahn, Weller, Barron, Klotz, Simpson, Duguid, Hunt, and many others, and forms in part their belief

in the reality of the increase." More recently Olson,⁸ Matz⁹ and Barnard¹⁰ supported the belief in the absolute increase in incidence. According to the statistical data at the Institute of Pathologic Anatomy,¹¹ a real increase in the frequency of cancer of the lung has been determined. Fried,¹² on the other hand, took the opposite view and subscribed to the belief that the increase is apparent rather than real, citing among other reasons increased availability of hospitalization and revolutionary improvement in diagnostic methods as applied to the chest, enabling clinician and pathologist to discover lesions which had been overlooked before.

Klotz⁷ mentioned that the dictum of Virchow with reference to the rarity of primary tumors in organs which are the site of metastasis may have been a traditional barrier to a diagnosis of carcinoma of the lung. He also mentioned the ability to recognize lesions once thought metastatic, sarcomatous or inflammatory.

ETIOLOGY

The etiologic factors in bronchiogenic carcinoma, as in carcinoma elsewhere, remain obscure. Chronic inflammatory processes, inhalation of irritating substances and hereditary susceptibility are all invoked because of their possible contributory importance. Fried¹³ cited thirteen cases in which, according to autopsy, there was coexistent tuberculosis. The tuberculosis was of a healing fibrotic type in all instances. Fried denied any causal relationship between the two conditions. Bronchiectasis, as a common inflammatory condition, can be considered more important as a resultant process than as a causative one. Thus Tuttle and Womack¹⁴ among seventy-six patients with bronchiectasis treated in the chest service at Barnes Hospital saw only one who subsequently had bronchiogenic carcinoma.

Olson⁸ found only an 8 per cent incidence of primary carcinoma in the lower lobe of the right lung, yet bronchiectasis or abscess is very common there.

With respect to pneumoconiosis, Vorwald and Karr¹⁵ stated that if inhaled dust is of etiologic importance the incidence of pulmonary tumor in pneumoconiotic persons should be higher than in the general population and the dust in question should be irritating to the lung parenchyma and capable of producing carcinomatous proliferation of epithelial tissue. In a significant number of autopsies the incidence of carcinoma of the lung in silicotic persons was no higher than in nonsilicotic persons. These authors said that only recognized carcinogenic substances, radium or tar can be considered possible factors from an inhalation standpoint.

The frequent occurrence of carcinoma of the lung in the Schneeberg mining district has been a cause for much speculation. According to Frissel and Knox¹⁶ this frequency may be related to radioactivity of the inhaled dust. Schmorl, also cited by Klotz,⁷ stated that the arsenic content of the dust might be an additional

From the Department of Radiology, St. Luke's Hospital. The pathologic data are presented through the courtesy of Dr. Edwin F. Hirsch.

Because of lack of space, this article is abbreviated in THE JOURNAL. The complete article appears in the authors' reprints.

factor. It is said that the incidence of carcinoma of the lung is decreasing at Schneeberg since the introduction of respirators, which suggests that the factors responsible for the pneumoconiosis are also related to the production of neoplasia. On the other hand, respirators have been used at Joachimstal and the incidence of tumors remains high, with pneumoconiosis uncommon. Silicosis is common elsewhere, but the related incidence of carcinoma is nowhere as great as in this mining district. Teleky¹⁷ stated that "practically, anthracosis and silicosis have no influence on the appearance of lung cancer."

It is worthy of note that according to Alwens and Jonas¹⁸ chronic pulmonary cancer has been included by the German government in its list of professional sicknesses retributable by obligatory indemnity. This disease presents a typical latent period following the occupation as chrome workers. Chrome dust induces inflammatory changes in the respiratory tract. The possible etiologic importance of chrome dust as an etiologic factor is verified by J. Lowy.¹⁹

From the experimental aspect Vorwald and Karr failed to observe any irritation, hyperplasia or tumor transformation of the epithelium lining the respiratory tract whether the dust was inert or whether it had caused fibrosis of pulmonary connective tissue. Seelig and Benignus²⁰ cited the work of Murphy and Sturm, who noted that in mice tarred in various areas of the skin primary tumors of the lung developed. These tumors were designated as a distinct type of epithelial tumor. Murphy and Sturm expressed the belief that tar painting has the constitutional effect of lowering the resistance of the animals and that local irritation grafted on the lowered resistance induces the formation of pulmonary tumor. The results were the same even if he painted area was excised. Andervont, cited by Seelig and Benignus,²⁰ secured the same results by injecting dibenzanthracene subcutaneously. This procedure evoked tumors in the lung earlier than at the time of injection. This worker accomplished local application of carcinogenic agents by covering silk threads with molten dibenzanthracene and passing them through mouths, some of the tumors being squamous cell tumors and some adenocarcinomas. Andervont expressed belief in genetic susceptibility because the incidence was higher in a group of animals that had a higher incidence of spontaneous cancer.

Seelig and Benignus²⁰ developed a method of direct application of tar to bronchial and alveolar surfaces without a high death rate. They first used soot swept from the stack of the power house furnace and then used tar free lamp black impregnated with a known quantity of established potent carcinogenic tar. The method was to substitute for the usual shavings used for bedding mice whatever variety of soot, lamp black or dust was to be tested. In six days soot particles were located in the small intrapulmonary bronchi. In five weeks the black particles were abundantly present in the smaller bronchi and alveoli and sparingly present in the interstitial tissue. The first group of experimental animals had four times as many tumors as did the groups of controls.

Schabad²¹ further showed that by introducing different carcinogenic chemical products (e. g. coal and tar) in different ways and in different places a considerable augmentation was noted in the quantity of primary tumors of the lung in mice. Schabad also established that the birth of these tumors had no connection with inflammatory manifestations. In a large number of cases such tumors can be produced by subcutaneous or intraperitoneal introduction of blastogenous substances, which completely excludes the necessity for penetration of the agent into the respiratory tract. Descendants of mice so treated have a special susceptibility for primary tumors of the lung. He concluded that experimentally the two principal theories of pathogenesis, inflammatory processes and aerogenous penetration of blastogenous substances, are not confirmed. Koelsch²² said that irritation due to inhalation of irritating substances is of no etiologic importance.

Hyde and Holmes²³ cited the work of Slye and her co-workers, who developed a strain of mice 100 per cent cancerous and also proved that cancer of the lung in mice is a recessive mendelian characteristic. The intrinsic factor of hereditary susceptibility to tumor formation in human beings is of far greater importance than the extrinsic or environmental factor, according to Klotz.⁷

PATHOLOGY

The primary growth is located more frequently on the right than on the left side, according to most statistical analyses,²⁴ although Fried¹² in a large series of autopsies found a negligible difference in distribution between the sides. The irregularities of growth render difficult satisfactory classification of gross lesions, and the macroscopic separation of tumors into different groups based on autopsy material is of questionable value.²⁵ Even at autopsy it often is impossible to relate the tumor to the bronchus of origin, chiefly because of the degenerative changes that often occur and because of the frequency with which secondary infection is superimposed on the neoplastic process. The widespread ramifications of the bronchial system throughout the lung permit an origin in any portion of the latter, but the site of predilection is the main bronchus or its larger branches. The hilar type of lesion is the most common.²⁶ The main bronchus and the bronchus to the lower lobe on each side are the favorite locations for the neoplasms, accounting for the site of origin in 85 per cent of the cases studied by Vinson.²⁴ Fried¹² expressed the opinion that the tumor always originates in the main stem of the bronchus or in some of its smaller branches.

Tumors other than the hilar type are variously designated, being called lobular by Geschickter and Denison²⁶ and nodular by Kerley.²⁷ The lobular type, described by Geschickter and Denison, arises at the periphery of the lung from the terminal ramifications of the bronchi. They stated that the hilar and lobular varieties are related to the primary embryonic and post-embryonic growth centers of the bronchial tree, the

former being the locality for bronchial proliferation and the latter for proliferation of the lung buds, whose evolution continues until late childhood. The lobular type is mentioned as being infiltrative in character, and cases are cited in which the infiltration has a miliary distribution. The nodular form is seen as multiple foci of pinhead to bean size which have a tendency to coalesce, raising the question of multicentric origin, and is hard to differentiate from multiple metastasis from an obscure primary growth. It may also be seen as a single peripheral lesion. An additional rare diffuse form is sometimes spoken of.⁷ This form may simulate a pneumonic consolidation or an interstitial fibrosis.

Histologically squamous, adenocarcinomatous (with or without mucous secretion) and anaplastic varieties are recognized. Fried²⁸ emphasized the importance of the basal cell layer in the origin of bronchiogenic carcinoma. He showed that the basal cells have marked

Fig. 1 (case 1).—Hip at time of admission. All symptoms referable to this lesion. Patient died in May 1936 and bronchiogenic carcinoma was found at autopsy.

potentialities for growth and are concerned with epithelial repair, being capable of differentiation into the specialized portions of the bronchial epithelium. Adler¹ in his case analysis stated that often it is difficult to distinguish the kind of epithelial cells that make up the tumor and its structural peculiarities: "One is frequently at a loss to decide whether in the section before him the cells are of epithelial or connective tissue origin, whether it is carcinoma or sarcoma." Adler stated also that the histogenesis was unsettled, being related to problems of epithelial metaplasia: "It is generally impossible to determine the histogenesis of a fully developed tumor." Even now, almost thirty years after Adler's observation, it is sometimes difficult to establish the histogenesis of bronchial neoplasms. It was his conviction that bronchial epithelium is a highly plastic material designed to accommodate itself in manifold ways to demands which local physiologic and pathologic conditions require. This view is sub-

scribed to by Tuttle and Womack,¹⁴ who expressed the opinion that hyperplastic and metaplastic lesions of the lung are protective rather than precancerous mechanisms. They stated that the ease with which bronchial epithelium becomes stratified and squamous explains the frequency with which this sort of epithelium is encountered in bronchiogenic carcinoma.

The importance of the basal cell layer in histogenesis, in accordance with Fried's theory, is affirmed by Edwards⁴ and Graham,³ and Klotz⁷ quoted Weller, who would depict graphically the histologic relationship between the different types of bronchiogenic carcinoma by a Y, the stem of which represents the anaplastic group. The two arms of the Y represent differentiation toward epidermoid or adenocarcinomatous types, the upper part of the arm indicating the highest degree of differentiation.

The squamous cell type of tumor is the most common,²⁹ but the classification of a tumor must be accepted with reservations, because different sections of the same tumor may present different microscopic features. A common cellular origin from epithelial basal cell deposits would predispose toward pleomorphism.³⁰ Thus in our series the tumor in one case was considered a sarcoma when tissue from a pleural portion was removed at thoracotomy. Later, on removal of the lung, the primary tumor was found to be a bronchiogenic carcinoma with extension to the pleural surface at the hilus.

The primary lesion spreads by way of the peribronchial lymphatics, and peripheral tumors often simulate metastatic or pleuritic growths. Pleuritic involvement may induce effusion into the pleural cavity. Extension to the regional and mediastinal lymph nodes is common, and mediastinal tumors may attain considerable size, not often, however, reaching the size of lymphoblastomas. Often the patient's initial consciousness of a pathologic process arises from a metastatic manifestation. Thus 12 per cent of Rogers'³¹ fifty patients who were examined post mortem went through the entire illness without a pulmonary symptom, and with 44 per cent a sign of metastasis was the initial symptom of illness. Arkin and Wagner³² in an analysis of 135 cases found predominant extrapulmonary signs and symptoms in one half.

The tendency of bronchiogenic carcinoma to cause widespread and early metastasis is well known. The situation of the lung in the circulatory system would favor generalized hematogenous dissemination.⁷ Tumor emboli from primary sources other than the lungs would tend to be filtered out in these organs and thus fail to reach remote foci. Central nervous system foci of metastasis, especially in the brain and adrenals, are a common observation. Adrenal involvement is said to cause a syndrome similar to Addison's disease. Extension to regional lymph nodes is most common, with the liver, abdominal lymph nodes, kidneys and bones other frequently observed sites. Rosedale and McKay³³ emphasized that metastatic bronchiogenic carcinoma is worthy of consideration in the case of any obscure intra-abdominal lesion.

Secondary pathologic features related to bronchial obstructions are common; the tumor may obstruct the bronchus by intraluminal growth or by invasion of the wall, producing constriction. Pressure on the bronchus by a peribronchial tumor is an occasional process; ulceration may or may not occur. Obstruction causes defective drainage,³¹ with consequent infection. Chronic bronchiectatic, suppurative, pneumonic and pleuritic phenomena in any combination may thus ensue. Atelectasis may complicate the obstruction and perpetuate the infection.

PROGNOSIS

The prognosis in all cases is very poor, the patient who lives two years after coming under clinical observation being exceptional. The prognosis is modified by the predominant cell type of the tumor and by secondary infectious processes induced by bronchial obstruction.

SYMPTOMATOLOGY

In our series of twenty-three cases the diagnosis in every instance was established by microscopic examination, on the basis either of biopsy or of autopsy. In eleven instances the diagnosis was determined by autopsy, in six instances by bronchoscopic biopsy, in two instances by operation and in one instance by punch biopsy. In three cases the diagnosis was presumed on the histologic character of supraclavicular lymph node biopsy.

The duration of symptoms before the patient seeks medical aid is often striking, and Farrell³⁶ found that more than one half of fifty patients did not seek medical advice until the first symptoms had been present for a year or more. We agree with Vinson²⁴ that all chronic pulmonary diseases have similarity of symptoms. Bronchiogenic carcinoma may simulate any condition, and the protean nature of its symptoms is borne out by a review of our series.

The symptoms are modified of course by the location of the neoplasm and the mechanical changes it induces in the bronchopulmonary system and the neighboring structures. The average age was 51, and all but four patients were males. It is well to remember that these tumors occur at an earlier age than one generally associates with malignant growth. McRae³⁷ found 50 per cent of sixty-one patients not over 45, while Stein and Joslin³⁸ found 65 per cent of 164 patients between 40 and 60.

Hemoptysis can probably be considered the chief subjective sign, and when presented by a patient of middle age it carries diagnostic significance and merits the suspicion of a bronchiogenic carcinoma. In our twenty-three cases, hemoptysis occurred eight times, or in 34 per cent of the cases, at some time during the clinical course of the illness. As the presenting complaint, hemoptysis occurred only three times. Dyspnea occurred nine times, or in 38 per cent of the cases, and was the presenting complaint twice, the clinical picture in one case being confused by the coexistence of decompensated syphilitic heart disease. Pain in the chest proved severe in eight cases, in five of which it was the presenting complaint. Productive cough was present in nine cases and was the chief complaint in

three cases at the time of admission to the hospital. Hoarseness occurred five times. In one case the upper lobe of the left lung was implicated, as established at autopsy, and this easily accounted for the presence of hoarseness. In the other four cases the hoarseness was not so easily explained. Dysphagia is an unusual symptom and was present once, being attributable to displacement of the lower part of the esophagus by the tumor.

Three, or 13 per cent, of the patients had no symptoms referable to the respiratory tract and no physical signs referable to the pulmonary lesion at any time during their illness:

CASE 1.—*Femoral metastatic carcinoma from a bronchus simulating osteogenic sarcoma.* P. W. H., a Negro aged 35, admitted to the hospital complaining chiefly of pain in the left hip of two months' duration, had no respiratory symptoms. A large, firm, fixed mass in the region of the greater trochanter was found. X-ray examination (fig. 1) revealed a destructive lesion not unlike an osteogenic sarcoma. A chest film (fig. 2) indicated the presence of a nodular area in the right side of the chest which had the appearance of a metastasis. Death occurred in May 1936, approximately four months after the onset of the patient's illness.

At autopsy a primary bronchiogenic carcinoma of the lower lobe of the right lung was found. The bronchus to the upper portion of this lobe for a length of 3 cm. had a tumor surrounding it like the cap of a mushroom. The tumor measured 7 by 6 by 7 cm. The lumen of the involved bronchus was not occluded. There was a metastatic carcinoma involving the left femur and the submental, cervical, axillary, inguinal, iliac, peri-aortic and left femoral lymph nodes. There was a pathologic fracture of the left femur. Histologically the tumor was of an anaplastic type.

Fig. 2 (case 1).—Area at right hilus which was thought metastatic from lesion of hip.

In five cases, including the three reported, there were presenting complaints due to a remote metastatic manifestation of the disease. Three of these five patients sought medical aid because of pain in some portion of the spine, two because of cervical pain. One patient complained chiefly of pain in the hip on admission and another of pain in the groin.

A history of a complicating infectious process was present in nine cases.

ROENTGEN SIGNS

The roentgenographic data on the chest in our cases showed a high degree of variability, as might be expected from the unpredictable growth behavior of the neoplastic lesions. The inadequacy of gross classification establishes the futility of roentgen classification. The more patients we see the more we are inclined to agree with Peirce³⁹ concerning the inconstancy of roentgen pattern. Manges³¹ stated that "the disease has no single characteristic roentgen sign. It appears in various locations, sizes, shapes and densities, involves

small or large area; causes varying amounts of displacements of organs, different degrees of functional interference, at times out of all proportion to the size of the actual growth." Christie⁵ added that "elaborate classifications have added little to our ability to make a correct diagnosis."

Fig. 3 (case 2).—Destructive process involving cervical spine in November 1933. No pulmonary signs or symptoms during illness. Autopsy in December disclosed very small bronchiogenic carcinoma.

The direct roentgen sign, and probably the one most suggestive of primary carcinoma, is the presence of a fairly homogeneous shadow, well defined, usually at or near the hilus. This shadow, however, may send extensions into the lung field.⁴⁰ Thus in case 1 (fig. 2) the dense, well circumscribed hilar shadow produced no modification in the shadow of the portions of the lung

peripheral to the lesion. In three other cases (15, fig. 5; 17, and 19, fig. 6) there were definite, circumscribed, oval or circular masses, one of which was separated from the hilus. In this connection it is interesting to note the hilar shadow in the left lung in a case in which the shadow was due to metastasis to regional lymph nodes from a primary lesion of the opposite lung.

The indirect roentgenographic signs are dependent on the modification in the shadow of the portions of lung peripheral to the site of the lesion. Thus there may be produced emphysematous or atelectatic phenomena consequent on partial bronchial obstruction or

obstruction. We have no cases illustrative of partial obstruction or obstructive emphysema, though such a mechanism has been described in connection with bronchiogenic carcinoma. Such cases have been recorded.⁴¹

In the event of obstructive emphysema, air finds ready entrance to the lung but difficult exit. Films taken during inspiration may show no abnormality; films taken during expiration show a definite mediastinal shift away from the side of the lesion.

A more common complication is the production of collapse of the lung or a part of the lung by complete obstruction by the tumor of the lumen of the bronchus supplying that portion of the lung. The mechanism of bronchial obstruction depends either on intraluminal growth of the tumor or on mural growth with constriction of the bronchus.⁴² In either instance the reduction

Fig. 4 (case 3).—Sagittal section of right lung obtained at autopsy.

in the size of the air passage may be accentuated by edema and thus may vary from day to day. The observations at autopsy may be misleading in that they show apparent patency of a bronchus, although films taken before death indicated probably complete obstruction.

⁴⁰ Carman, R. D.: Primary Cancer of Lung from Roentgenologic Viewpoint, *M. Clin. North America* 5: 307 (Sept.) 1921. Manges.⁴¹

⁴¹ Manges, W. F.: Bronchial Neoplasms: Roentgenologic Aspects, *Arch. Otolaryng.* 12: 732-738 (Dec.) 1930.
⁴² Hirsch, I. S.: Roentgen Diagnosis of Malignant Neoplasms of Lung, *Radiology* 9: 470-496 (Dec.) 1927. Christie.²

In one instance the primary tumor involved the bronchus to the upper lobe of the left lung, yet there was a marked compression atelectasis of the lower lobe, accompanied by bronchiectasis. Here the tumor involving the bronchus to the upper lobe had apparently produced external compression of the bronchus to the lower lobe. The atelectatic process is of slow development when compared to the atelectasis of foreign body origin.⁴³ Thus in one case two films taken six weeks apart showed the slow progress of an atelectatic process. Kerley²⁷ expressed the opinion that deaeration of the lung begins in the least expansile portions, that is, at the apex or in the periphery just below the clavicle, especially with involvement of a bronchus to an upper lobe. He also said that mediastinal shift is greater with lesions of a lower lobe than with lesions of an upper lobe. In one case, mediastinal shift due to an obstructing mass in the left main bronchus was demonstrated. The homogeneous opacity is partly due to pleural fluid. In addition there was narrowing of the esophagus, an uncommon observation.

Complete or partial collapse of the lung creates a favorable nidus for infection, probably on the basis of defective drainage, an infectious process furnishing the background for frequent complications. Thus the massive obstructive pneumonia involving the lower and middle lobes of the right lung and the empyema account for one picture observed. Also the breakdown of tissue at the site of the lesion in the upper lobe of the right lung produced a picture which simulated a pulmonary abscess. The upper lobe of the left lung in one case was occupied by a bronchiectatic and suppurative pneumonic process. Pleural fluid may be the result of extension of parenchymal infection of the lung or may perhaps be the result of pleural metastasis.

For clarification of the nature of the roentgen signs of fluid, tumor masses or obstructive phenomena in cases in which there is a possibility of bronchiogenic carcinoma, the usual examination of the chest should be supplemented by lateral and oblique views. In the presence of a large, homogeneous shadow occupying the greater portion of a lung field, a "hard" film may localize a definite tumor mass or be of definite value in establishing the site of pathologic change. Films taken after thoracentesis are to be recommended. Roentgenoscopic examination is an important phase of the examination, and bronchograms are useful. The value of films taken during different phases of respiration has been mentioned.

An additional change occasionally observed is the presence of an infiltration process extending outward into the lung field. This was well illustrated in one case in which the diffuse infiltration was due to pulmonary lymphatic dissemination from a relatively small primary tumor involving the right main bronchus.

In recapitulation, we had direct evidence of a tumor in only six cases. In thirteen cases the presence of tumor could be inferred only from evidence of secondary pathologic processes. In four cases the roentgen evidence of tumor was vague or lacking entirely.

The roentgenologist occupies a pivotal position in the elucidation of positive signs referable to the chest and, working in close cooperation with the bronchoscopist, can render the early diagnosis of bronchiogenic carcinoma more of a certainty when the internist's evaluation of the history suggests the possibility of such a lesion. Bronchoscopic examination should be done

in all cases of obscure involvement with evidence of bronchopulmonary pathologic change.⁴⁴

From the standpoint of differential diagnosis the following points are offered, though we recognize the definite limitations in their usefulness: Tumors of the lymphoblastoma group are apt to produce more embarrassment of mediastinal structures; their shadows are usually larger, they are nodular and often bilateral and they are much more radiosensitive, a differential point in diagnosis of great value.³⁴ Dermoid tumors are always connected with the anterior mediastinum, often cast a homogeneous, rounded, well encapsulated shadow and may show calcification.⁴⁵ Osteoma of a rib or osteochondroma of the sternum can be identified with their places of origin by careful roentgen study in different projections. Neurofibroma occasionally produces a dense shadow in the lung field, but changes in the dorsal vertebrae can usually be determined if proper films are taken. Neurofibroma is probably the commonest tumor of the posterior mediastinum. Paravertebral shadows and cardiovascular lesions are unlikely to be confused with bronchiogenic lesions. The usual discrete nodular character, multiplicity and frequent bilaterality of pulmonary metastatic foci are distinguishing features. However, pulmonary metastas-

Fig. 5 (G. C.).—Chest in two views showing tumor of right lower lobe. Patient died in June 1938, several days after lower and middle lobes were removed.

sis may be massive and infiltrative⁴⁵ and primary carcinoma may have a miliary distribution, and differentiation at times is impossible.

With distinguishing pulmonary lesions due to foreign body the history is of great importance.⁴¹

Inflammatory conditions of an acute nature may initiate the clinical picture of a bronchiogenic neoplasm, and only when convalescence is unduly prolonged does a primary malignant process become suspected. Chronic inflammatory processes are, in the majority of instances, bilateral. An exception is noted in the case of foreign body. In this regard it is rare indeed when the history will not establish the diagnosis of foreign body.

Tuberculous lesions of sufficient size to offer diagnostic difficulties evolve in one direction or the other in a relatively short period of observation. The hilar region, a common location for tumor, is a rare site for adult tuberculosis, and even more rare would be hilar tuberculosis without a parenchymal lesion.

SUMMARY

The pathologic, clinical and roentgen features of twenty-three proved cases of bronchiogenic carcinoma emphasize the protean manifestations of this disease.

43. Golden, R.: Effect of Bronchostenosis upon Roentgen Ray Shadows in Carcinoma of Bronchus, *Am. J. Roentgenol.* 13: 21-30 (Jan.) 1925.

In conclusion we quote an important and pertinent statement made by Dr. G. W. Scupham, of Chicago: "Whenever pulmonary symptoms, particularly dyspnea and pain, are out of proportion in their severity to x-ray or physical findings, bronchiogenic carcinoma is likely."

ABSTRACT OF DISCUSSION

DR. LEROY SANTE, St. Louis: All will agree with the authors about the inconsistencies of the x-ray appearances in bronchogenic carcinoma in the chest. Their wide variety is notorious and it is a challenge to see whether we cannot bring some order out of chaos. If we bear in mind the two fundamental types of involvement described by Ewing, it will at least afford a basis on which to formulate the diagnosis. The nodular type of carcinoma that tends to remain local springs from the superficial layers, grows as a nodule and by occlusion leads to atelectasis. The second type springs from the deeper bronchial layers, has a tendency to metastasize, has a tendency to break down in the center forming abscesses, and simulates a pyogenic abscess so closely that one cannot tell them apart, even at autopsy. If these facts are borne in mind and the x-ray observations are correlated with the clinical symptoms, we shall have a better opportunity of arriving at a correct conclusion. One is dependent here more on correlation with the clinical history than in any other condition in the chest. The relatively long duration of carcinomatous conditions without febrile reaction is a point to which a great deal of weight should be given. If, in addition, there is bloody expectoration, this is additional evidence of carcinoma. If one has the opportunity of examining a patient over a considerable period of time and can see an increase in the size of the lesion, it becomes evident that one is dealing with a new growth. With massive lesions in the chest especially when there is a febrile reaction the difficulties begin and sometimes it is almost impossible to determine the true nature of the condition. If massive atelectasis suddenly develops without any other evident cause, it is a manifestation of the nodular type of carcinoma, which occludes the bronchus. Occasionally lesions develop on the pleural surface, giving rise to pleural effusion. Aspiration of some of the fluid, allowing a little air to get in, will permit one to see the character of the lesion on the surface. Massive involvement may present difficulties. A lateral view may show such enormous masses extending from the posterior wall of the chest. Such a condition may, in the presence of a febrile reaction, give one the impression of a localized effusion. Still other cases occur in which localized pleural effusions give the appearance of rounded nodules in the region of the interlobar space, resembling tumor. In subsequent examinations in a few weeks these may show increase in size from accumulation of fluid which could easily be mistaken for carcinoma.

DR. ROSS GOLDEN, New York: By analysis of a series of cases like this made by Drs. Jenkinson and Hunter, our knowledge of the x-ray manifestations of these processes is improved. A point worthy of emphasis is the importance of the physical situation of the growth in the x-ray appearances and in the clinical evidence of the disease. The growths which arise out in the periphery manifest themselves differently both on the x-ray films and clinically from those in the larger bronchi. The growths that arise in the larger bronchi cause earlier and more serious disturbance in the pulmonary function and the symptoms are likely to be based on that disturbance for a while. Another point to emphasize is the value of injecting iodized oil through the glottis. It does not have to be done by bronchoscope but can be done through the glottis. Very important information may be thus obtained. The importance of bronchoscopy itself in the diagnosis of carcinoma of the bronchus must not be forgotten.

DR. R. G. TAYLOR, Los Angeles: There is one thing in connection with the diagnosis of these cases that has not been mentioned; probably it has only been overlooked. That is, in these dense areas in which the ordinary film gives no detail, an overexposed film or one made on the Bucky diaphragm gives more detail in the dense lung areas. It is worth trying and frequently one gets additional information.

DR. EDWARD L. JENKINSON, Chicago: We did not show slides or films for one specific reason. Dr. Hunter and I have been working on this paper for about two years, and we have gone over numerous films with the idea of picking x-ray appearances which might be characteristic of primary lung neoplasms. From our experience we have been unable to determine anything characteristic of neoplasms from the x-ray appearances. The shadows were usually bizarre and might well be due to various other diseases. From our experience we believe that bronchiogenic carcinoma is still a diagnostic enigma. We concur in what Dr. Sante said with regard to serial films. They are an aid, along with clinical observations, in at least arousing one's suspicions that a malignant condition exists. Two of our patients showed only small infiltrating lesions along the left upper lobe bronchus. The patients were in an excellent state of health and complained only of a slight pain in the upper left chest. From the x-ray appearances it was impossible to differentiate these lesions from many other lesions which might occur in the upper lobe. Dr. Chevalier Jackson examined one of these patients with the bronchoscope, but as the lesion was in the left upper bronchus it was impossible to get a specimen. The injection of iodized oil revealed a blocking of the left upper lobe bronchus. When the patient was irradiated the upper lobe lesion completely disappeared. Later on Dr. Jackson found a squamous cell carcinoma, proved at biopsy, in the left main bronchus. We agree with Dr. Taylor that overexposed Bucky diaphragm films will often be of aid in recognizing neoplasms in the lungs. The planograph, we believe, is of greater value than the dark film. Fever was present in many of our reported cases.

RECONSTRUCTIVE AND STABILIZING SURGERY

FOR RESIDUAL SUPPURATIVE ARTHRITIS OF
HIP JOINT: A STUDY OF FORTY-SIX
UNSELECTED CASES

HALFORD HALLOCK, M.D.
NEW YORK

Between the years 1919 and 1937, thirty-eight patients had forty-six operations at the New York Orthopaedic Dispensary and Hospital for the reconstruction or stabilization of a hip joint that had been damaged or destroyed by previous suppurative arthritis. The experience with these cases and the results that have been obtained are now reported. After a careful review of the histories and roentgenograms, it is felt that all these persons had actually had suppurative arthritis.

The operations consisted of twenty reconstructions, four arthroplasties, seven shelf stabilizations and fifteen fusions, and they will be discussed in this order. There were no operative deaths. One patient, a child, died six years later from spinal meningitis.

THE RECONSTRUCTIONS

Reconstructions numbered twenty and were performed on eighteen patients, who varied in age from 1½ to 17 years and averaged 9. Two each had a second reconstruction on the same hip one year later. The average time of operation after the initial infection was six years, varying from fourteen months to sixteen and one-half years.

The amount of joint damage was staggering. Extensive destruction of the femoral head and neck was the rule, and 70 per cent of the hips were dis-

located. The type of original infection is not known except in three cases, in two of which it was due to a staphylococcus and in one to a pneumococcus. There were no draining sinuses at operation. Drainage occurred postoperatively in two cases, or 10 per cent. At follow-up examination all patients were free from sinuses.

Fig. 1.—Reconstruction in S. B., a girl of 9 years; bifurcation procedure. A, before operation; B, eight months after operation; C, eight years after operation. Result: no pain, flexion mobility 40 degrees, index 23, dislocation cured, shortening 1 inch and moderate limp. The patient dances, skates and can walk thirty-eight blocks.

The type of reconstructive procedure varied chiefly in relation to the extent of joint damage. In general, if sufficient length remained, the neck was shaped and placed in the acetabulum and the trochanter was usually transplanted downward (five cases). If the neck had been completely destroyed, the end of the femur was bifurcated, the outer or trochanteric portion wedged outward and the medial portion reduced into the acetabulum (eight cases). In four cases the trochanter or abductor attachment alone was moved downward, and the end of the shaft was placed in the acetabulum. In one case with bony ankylosis, a supporting ledge or

shelf of bone was fashioned beneath which the liberated end of the femur was placed. Bony ankylosis recurred. In another case with marked overproduction of bone a naturally formed ledge was utilized as a shelf, and the reshaped upper end of the femur was placed in a notch beneath it. This patient when last seen, a year later, had 70 degrees of painless anteroposterior mobility and a stable hip. A Colonna procedure was employed in one case but failed, primarily because of insufficient acetabular depth. The acetabulum was made deeper in half the cases exposing bone in two and probably in five. An entirely new acetabulum was constructed in one. In two cases a shelf was also turned down from the ilium over an insufficient and oblique socket.

All patients were placed in plaster spicas after operation, and motion was begun in from one and one-half to twenty-eight weeks with an average of twelve. The records do not state why immobilization was continued

for so long, but the most probable reason was the high percentage of preoperative dislocation and attendant instability.

Physical therapy was given in the forms of massage and exercise and was continued as long as the patient was in the hospital and as long as he would return to the clinic.

Results.—Follow-up examinations were made on all the patients from one to fifteen years after operation with an average of six years; expressed as case years, the average time was eleven.

Pain: Three patients had pain before operation and five, or 28 per cent, after. The low incidence of preoperative pain was probably due to the youth of the patients (average 9 years) and to the high proportion of dislocation (70 per cent). The relatively low percentage of postoperative pain, 28, is gratifying; but

TABLE 2.—Index of Function of Hip Expressed in General Terms

	Index
Hypermobile.....	Over 110
Normal.....	90-110
Good.....	60-90

only four of the patients have reached adult age. These four, now ranging in age from 20 to 28 years, are without pain, but two have had a recurrence of bony ankylosis, one a thin joint space with irregular articulating femoral surface and practically absent motion (index 2, described in the next section), and another a smooth stump of femoral neck articulating with a small residual socket and presenting an index of 28. It is probable that when the rest of these patients have been followed into adult life a higher percentage of pain will be found.

Motion: In order to express simply and completely the range of mobility in any given hip joint, the index of function was used that was described by Ferguson and Howorth.¹ To obtain this index, the degrees of

Fig. 2.—Reconstruction in W. Y., a boy of 13 years; bifurcation procedure. A, before operation; B, eight months after operation; C, thirteen years after operation. Result: no pain, index 2, shortening 1½ inches and moderate limp. The boy plays baseball and basketball and can walk 5 miles.

motion present in each arc of mobility are multiplied by a suitable factor the size of which depends on the relative importance of that particular arc for function of the hip as a whole. The products are added, and the sum is the index of function. The normal hip has an index of from 90 to 110. Table 1 is an illustration.

1. Ferguson, A. B., and Howorth, M. B.: Slipping of Upper Femoral Epiphysis, J. A. M. A. 97: 1867 (Dec. 19) 1931.

Before operation 70 per cent of the hips dislocated, and the index of function varied from 0 to 110 and averaged 64. After operation 20 per cent dislocated, and the index ranged from 0 to 69, averaging 20. Three operations resulted in bony ankylosis. The results are presented in table 3.

Dislocation: This complication was present preoperatively in fourteen cases, or 70 per cent, and was

Fig. 3.—Reconstruction in C. M., a girl of 8 years; bifurcation procedure. A, before operation; an unsuccessful reconstruction was performed on this hip one year previously; B, three months after operation; C, thirteen years after operation. Result: no pain, occasional stiffness, flexion mobility 35 degrees, index 23 and shortening 2 inches. The patient works in an office, dances and walks sixteen blocks a day in the city and a great deal in the country on week ends.

relieved by operation in all but five. Postoperative roentgenograms showed that in four cases the displacement was present immediately after operation. Manipulations were done in three cases, unsuccessfully in two and successfully in one but followed later by redislocation. The fourth hip joint was considered to be stable enough, although subluxated, and was not manipulated; but dislocation occurred subsequently. The fifth joint, treated by a Colonna reconstruction, dislocated after eight weeks when taken out of plaster because of insufficient acetabular depth.

Shortening: The average amount was $1\frac{1}{2}$ inches (3.8 cm.) before operation and the same after. It varied from one-fourth inch (0.6 cm.) of lengthening in one case, due to osteomyelitis and shortening of the opposite tibia, to 3 inches (7.6 cm.).

Limp: Preoperatively, every patient had a limp; and at follow-up examination, except for one instance in which a specific statement was not made, a limp was present in each case. The limp was not usually described before operation; but after, it was noted as severe in six cases, moderate in six, slight in three and merely present in four. In all the six cases in which there were marked limps, mobility was absent or greatly restricted, and there were also present one or more of the following factors: pain, dislocation, shortening of 1 inch (2.5 cm.) or more and pronounced flexion or adduction deformity (over 35 degrees of the former and 15 degrees or more of the latter).

Subsequent Operations: Nine subsequent operations were performed on eight patients. These included one open release of hip flexion deformity, one arthroplasty, one shelf stabilization and four fusions, all performed on previously reconstructed hips, one supracondylar osteotomy for external rotation deformity and one for anteversion of the femoral neck.

THE ARTHROPLASTIES

In four cases conditions were such as to make possible the fashioning of a more or less characteristic articulation with the employment of interposed tissue.

These procedures have been designated as arthroplasties in contradistinction to the reconstructions that have just been discussed.

The ages of the patients varied from 14 to 17 years, and the average time of operation after the original infection was six years. The organisms responsible for the joint damage are not known, but in one case *Staphylococcus aureus* was cultured from the bone at operation. Two of the patients presented a bilateral bony ankylosis and one a fibrous ankylosis on one side (index 6) and a bony ankylosis on the other. They were extremely handicapped. The fourth had a unilateral fibrous ankylosis with a functional index of 5. There were no dislocations.

In the cases of bony ankylosis, new heads and sockets were constructed out of solid bone; in the two with fibrous ankylosis, both femoral heads were made much smaller, and in one the acetabulum was made deeper.

The tissue that was interposed consisted of a double layer of fascia lata in one case, a single layer in two cases and a thick peduncular flap of fibrous tissue in another case.

None of the patients had sinuses at the time of operation. Preoperatively, they had been present in two but had closed three and six years before. In the other two, it is not recorded whether sinuses had ever been present or not. Three patients developed drainage after operation, after ten days, three months and seven months, respectively. It was in this first case that *Staphylococcus aureus* was cultured at operation, although all sinuses had been closed for three years.

At follow-up examination, all patients were without sinuses.

Plaster was applied after operation and in addition skin traction was used twice. Motion was begun in from three to six weeks, the period averaging four weeks. Manipulations under anesthesia were given in one case to maintain motion, but subluxation resulted, and bony ankylosis recurred.

Results.—The average time of follow up examination was eight case years and varied from four to fifteen years.

Pain: Before operation, only one patient complained of pain, and after, also only one. The patient who

Fig. 4.—Arthroplasty in A. S., a girl of 14 years. About three fourths of the head was resected, and a single layer of fascia lata was interposed. *Staphylococcus aureus* was cultured from the bone at operation, and sinuses developed on the tenth day. A, before operation; B, one year after operation; C, three and one-half years after operation. Result: no pain, flexion mobility 20 degrees, index 4 and no sinuses.

previously had pain, a boy of 17 with a fibrous ankylosis of one hip and an index of 5, was entirely relieved; at present, fifteen years later, at the age of 32, he has 50 degrees of flexion mobility but limited lateral motion and rotation. The patient who since operation has had pain and who previously had a bony ankylosis of both hips now has a sensitive fibrous ankylosis with only 5 degrees of anteroposterior mobility.

Two patients have reached adult age and are free from pain. One, however, has a recurrent bony ankylosis, and the other, the man of 32, a movable hip with a fair range of flexion mobility.

Motion: Before operation, two patients presented bony ankylosis and two fibrous, both with indexes of 10. After operation, in the first two bony ankylosis

Fig. 5.—Arthroplasty in H. F., a boy of 17 years. The preoperative film has been discarded. The femoral head was considerably reduced in size and the acetabulum was made deeper. A single layer of fascia lata was interposed. Motion was begun at three weeks. A, two and one-half years after operation, and B, fifteen years after operation. Result: no pain, flexion mobility 50 degrees, index 26, shortening $1\frac{3}{4}$ inches and slight limp.

redeveloped and the other two obtained motion with indexes of 5 and 26.

Limp: All four patients limped preoperatively, three badly because of bilateral involvement and absence of motion. After operation, these three still limped severely because of recurrence of bony ankylosis in two and failure to develop any more than a slight amount of motion in the third. The one patient with unilateral involvement, the man now 32 years of age, walks extremely well and has only a slight limp. He has a

		20

flexion and external rotation deformity of respectively 20 and 35 degrees, $1\frac{3}{4}$ inches (4.5 cm.) of shortening and excellent flexor, extensor and abductor hip muscles.

THE SHELF STABILIZATIONS

In seven cases, with dislocations in six and subluxation in one, shelves were constructed above the displaced femurs to achieve stability and preserve motion. In six the shelves were turned down from the ilium, and in one a section of iliac bone was turned outward and upward and the intervening space filled in with fragments of bone.

The patients varied in age from 2 to 19 years and averaged 10. The time of operation after the original infection also ranged from two to nineteen years, averaging nine. The disease began in one at the age of 3 weeks.

Two of the patients complained of pain, and all had a limp. The average amount of shortening was 1.7 inches (4.3 cm.). No sinuses were present at opera-

tion or at follow-up examination, and none developed postoperatively. The causative organisms are not known except in two cases, in both of which it was a pneumococcus.

Postoperative x-ray films demonstrated adequate shelves in five cases. In one the shelf was placed too high, but the femur in later years either grew or ascended to its level and finally came to rest securely beneath it. In another case the shelf was placed too obliquely. It was revised but two months later had become again too oblique. A second revision was performed, and the shelf was also moved down three-eighths inch (1 cm.); but subsequent x-ray studies revealed still too high and oblique a position. In six years the femur had either grown or ascended to the level of the shelf but would not remain beneath it except while traction was maintained on the leg. This patient was only $2\frac{1}{2}$ years old at the time of operation, and the shelf was turned down from the ilium. It is now our custom to postpone shelf stabilization if possible until the child is a few years older and the ilium is better developed, and to drive a free graft of iliac bone into the ilium immediately above the displaced femur to obtain accurate placement more readily.

Results.—Follow-up examination varied from one and one-half to twelve years after operation and averaged six case years.

Fig. 6.—Shelf stabilization in M. S., a boy of 5 years. A large mass of bone was turned up and outward, and the resultant triangular space was filled with bone. Too high a position was obtained, but in later years the femur grew and ascended to the level of the shelf. A, before operation; B, five months after operation; C, one and one-half years after operation; D, nine years after operation. Result: slight pain only when roller skating, flexion mobility 75 degrees, index 46, abductor muscle power 70 per cent of normal and marked limp. The shelf offers oblique support. The patient works as a grocery clerk and is on his feet all day without any trouble.

Stability: X-ray observation at the time of follow-up examination revealed three adequate shelves, two instances of complete shelf absorption and two dislocations from beneath a shelf. In one of the latter, the shelf was ineffective because of too much obliquity. In the other, it appeared to be adequate, but beneath

it there was a laterally protruding ledge of bone that was apparently levering the femur out of place.

The shelves that underwent complete absorption had been turned down in two patients respectively 10 and 15 years of age. Postoperative x-ray films showed apparently well constructed shelves placed within one-fourth inch (0.6 cm.) or less of the end of the femur.

Fig. 7.—Shelf stabilization in F. S., a boy of 15 years. The femur was pulled down, and a shelf was turned down from the ilium. A, before operation; B, immediately after operation; C, seven years after operation. Result: frequent pain on beginning to walk, flexion mobility 115 degrees, index 66 and complete absorption of the shelf. The patient can walk several miles but had to give up delivering groceries because of pain.

Absorption was noted in one after three months and estimated at 60 per cent in the other after ten months. One shelf, placed too high in a boy of 5, underwent partial absorption, which fortunately was insufficient

to jeopardize the stability that was later obtained after upward growth or ascension of the femur.

Pain: Two patients complained of pain before operation and four after. Two of these had pain before stabilization and two had not. The pain at follow-up examination was moderate in one, frequently occurring on beginning to walk, slight in two when they were roller skating and playing too much football, and so severe in the fourth, a woman of 22, as to necessitate hip fusion three years later. The shelf in this case was quite adequate, but irregularity of articulating surfaces had developed between the femur, the shelf and the ilium. As for the three other patients, who had only slight or moderate pain, the shelf had completely absorbed in two but appeared to be adequate in one.

Motion: Before operation the functional indexes varied from 27 to 100 and averaged 75; at follow-up examination they ranged from 24 to 83, averaging 51.

Shortening: This varied from one-half inch (1.3 cm.) of lengthening in one case, due to accompanying involvement and dislocation of the opposite hip, to 2½ inches (6.3 cm.). The average amount of shortening was 2 inches (5 cm.); 1.7 inches (4.3 cm.) before operation.

Limp: Preoperatively a limp was noted as merely present in four cases, moderate in two and severe in one. At follow-up examination it was described as moderate in four and marked in three. Each of these three patients with a severe limp had 2 inches (5 cm.) or more of shortening, two had pain, and in one the shelf had completely absorbed. In addition, abductor muscle power was markedly weak in two and about 70 per cent of normal in one.

THE FUSIONS

Fifteen patients had hip fusion operations. All had unilateral lesions, and five had dislocations. Four patients had previously had reconstructions, and one had a shelf stabilization later. These procedures had all failed, because of pain in two cases, dislocation and pain in one and severe flexion deformity with fibrous ankylosis in another. The ages of these patients varied from 8 to 41 years and averaged 18. The time between the original infection and operation ranged from three to twenty-two years, averaging twelve.

In only two cases was the infecting organism known, and in both of these it was a pneumococcus. Material for cultures was taken at operation from half the patients, but a growth was not obtained in any instance.

A sinus of eight months' duration was present in one case at the time of operation. Fusion was proceeded with, however, because it was thought that the hip might be tuberculous, but only chronic nonspecific inflammation was found on microscopic examination of tissue specimens. Postoperative drainage occurred in three cases. This was probably caused in two by

Fig. 8.—Fusion in H. A. V., a girl of 13 years. A, before operation; B, eleven years after operation. Result: no pain, solid arthrodesis in 45 degrees flexion, 10 degrees abduction and 10 degrees internal rotation, shortening 2 inches and moderate limp.

wound infection. None of the patients had sinuses at follow-up examination.

The presenting complaint was pain in ten cases and stiffness, weakness, severe deformity and marked limp in four others.

The type of fusion operation varied. In nine cases a Hibbs procedure was used in which the anterior two thirds of the greater trochanter and part of the shaft were removed, with or without an attached muscle pedicle, rotated 180 degrees and driven into the ilium

ARTHRITIS OF HIP JOINT—HALLOCK

2403

over the bared neck or upper extremity of the femur. Bone chips were also placed about the transposed trochanteric mass, femur and ilium in a few instances. In three cases grafts from the ilium were employed, augmented twice with chips. In two cases fusion was made with suitably placed multiple small bone transplants. In two others direct contact was made between the end

Fig. 9.—Fusion in R. T., a girl of 14 years. A, before operation; B, six years after operation. Result: no pain, solid arthrodesis in 40 degrees flexion, 10 degrees abduction and neutral rotation, shortening 1½ inches and slight limp.

of the femur and the acetabulum or ilium. Bone chips were also used in one of these and a steel nail for fixation in the other.

In half of the cases, cartilage and bone were removed from the inner or superior portions of the joint in order to secure intra-articular fusion as well as arthrodesis through the grafts. Any resulting space was usually filled in with bone chips.

In general, walking in plaster was permitted at three months; as soon as clinical and x-ray examinations indicated that the arthrodesis was secure enough, plaster support was discontinued. This took place on the average after six and one-half months.

In each of four cases a subtrochanteric osteotomy was subsequently performed in order to obtain proper position. This was necessary in three cases owing to the fact that in each arthrodesis was done in the presenting malposition, for this could not be changed without undue exposure and traumatism with consequent increased risk of reactivation of infection. In the fourth case, in which fusion had failed, osteotomy was performed to relieve a persistent backache due to excessive hip flexion deformity with accompanying exaggerated lumbar lordosis. Rearthrodesis was refused.

Two operations were necessary in one case, in which the most likely cause of postoperative drainage was a deep wound infection, as culture of the bone at operation yielded no organisms. A fusion was obtained, however, within six months, but sinuses persisted for four years.

Results.—The time of follow-up examination varied from one and one-half to thirteen years and averaged five or seven case years.

Attainment of Fusion: Eleven, or 73 per cent of the patients, obtained fusion by primary operation and four failed to do so. Later three of these had a secondary or refusion operation with success in two and failure in one. The fourth has refused further surgical treatment because the hip has remained painless. In all, thirteen, or 87 per cent, of the patients have fused joints and are symptomless at the present time.

Pain: Ten patients, or two thirds of the group, had pain before operation; at follow-up examination, only one. This is the case in which refusion failed and a third operation was advised.

Shortening: The average amount of shortening was 1.7 inches (4.3 cm.) before operation and 1.9 inches (4.8 cm.) after.

Limp: Preoperatively a limp was present in every case. It was severe in three cases, slight in one and present but not described in eleven. At follow-up examination two patients had a severe, six a moderate and five a slight limp. In one case it was merely noted as being present; and in another no statement was made. One of the patients with a severe limp did not obtain a fusion and has pain; the other, with solid fusion, has 4½ inches (11.43 cm.) of shortening.

With fusion, the resultant limp, unless shortening is marked or a good position is not obtained, is generally much less than before because pain, instability, abductor muscle weakness and malposition are no longer participating factors. With arthrodesis in good position and without too much shortening, the limp is only slight and not very noticeable.

Optimal Position for Arthrodesis: This has been found to be 20 or 25 degrees of flexion, neutral lateral or 5 to 10 degrees of abduction, depending on the amount of shortening present, and neutral or slight external rotation.

In this series at follow-up examination, the anteroposterior positions varied from 25 to 60 degrees, averaging 35. Severe flexion deformity, over 35 degrees, occurred three times. Ten degrees or more of adduction was found in three cases, internal rotation in three and excessive external rotation in three.

COMMENT

The experience with these relatively small series of cases indicates that reconstructive procedures in children generally result in control of dislocation and painless hips but with considerably limited ranges of mobility (table 4). Absence of pain, however, may not be permanent; for as these patients reach adult age

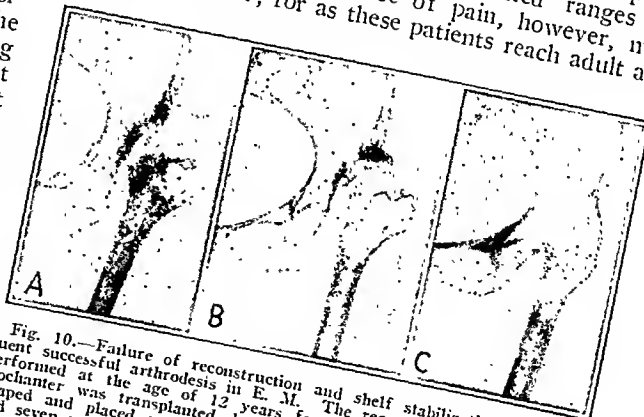

Fig. 10.—Failure of reconstruction and shelf stabilization and subsequent successful arthrodesis in E. M. The reconstruction operation was performed at the age of 12 years for a painful dislocated hip. The trochanter was transplanted downward, and the end of the shaft was shaped and placed in the acetabulum. Dislocation and pain recurred, and seven years later a shelf was turned down from the ilium. Severe pain continued, and three years subsequently an arthrodesis was performed with complete relief of symptoms. A, seven years after reconstruction operation and just before shelf stabilization. B, three years after shelf stabilization and just before arthrodesis. C, three years after arthrodesis. Result: solid fusion in 35 degrees flexion, 10 degrees abduction and neutral rotation and shortening 2 inches. The patient walks long distances.

pain will probably develop in many because this type of operation does not produce a very good joint mechanically. The arthroplasties accomplish this much better, but unfortunately many of the patients do not have

enough residual bony structure for this type of plastic procedure.

Well constructed and well placed shelves, unless absorption ensues, will provide dislocated hips with stability and fairly good ranges of motion. They will also check possible progressive ascendancy of the femur on the ilium with consequent increased shortening. Unless considerable irregularity of joint surface develops between femur, shelf and ilium, these hips should remain practically painless in adult life, but because of shortening and abductor muscle weakness, the patients will probably have marked limps.

It is the fusions, however, that can be relied on to provide stable hips free from pain and without marked limp unless a poor position is obtained or there is too much shortening. The best results are secured with unilateral involvement; but even when it is bilateral fusion may be indicated in combination with a mobilizing procedure on the opposite side in order to assure the patient of at least one painless and stable hip.

The previous presence of suppuration does not seem to be an absolute contraindication to a mobilizing procedure, but persons showing a marked proclivity to overgrowth of bone or evidence of considerable previous osteomyelitic involvement of juxta-articular bone which would have to be extensively opened at operation should probably not have a reconstruction or arthroplasty because of the prospect of further overgrowth of bone or reactivation of dormant bone infection. Fusion, if not already present, would be more advisable in such cases.

In deciding on a mobilizing operation, careful case selection should be made. For example, patients whose periarticular structures have become extensively scarred or whose muscles have been inactive following a longstanding ankylosis of the joint are not good subjects for procedures designed to secure or enhance motion. Probably very little movement can be maintained, and failure will result. Arthrodesis is again the operation of choice unless a mobilizing procedure is made mandatory by bilateral involvement, in which event the increased risk of failure must be accepted.

The time of operation is of great importance. It is advisable to wait at least two or three or even several more years after the cessation of all drainage or other evidence of activity.

Finally it must be emphasized that the only way to decrease the number of unfortunate persons requiring reconstructive and stabilizing surgical procedures because of the ravages of suppurative arthritis is to make an early diagnosis and to drain the joint immediately and adequately. The diagnosis must usually be made clinically, as x-ray changes in the bone are late and cannot be awaited. If the diagnosis is in doubt, an exploration with negative results is far better than to allow undrained pus to produce more and more involvement of circulation and destruction of bone.

410 East Fifty-Seventh Street.

ABSTRACT OF DISCUSSION

DR. J. ALBERT KEY, St. Louis: Every reconstruction operation is a subterfuge. One does not know what else to do. I have never seen a reconstruction operation that I liked and the same is true here. I believe that a great many of these patients would have been a lot better off with a subtrochanteric osteotomy and no surgery on the hip joint. Preliminary traction should be given before a shelf operation is done. I realize that in old septic hips there is so much fibrous tissue that one cannot do much with traction; on the other hand, a preliminary loosening up can be followed by wire traction and

then placement of the shelf and postoperative treatment in a plaster cast, leaving the wire in the femur and fixing it in the cast in order to hold it down. The reason shelves absorb is because they do not function. The shelf does not have to be very large but it must be in the right position. If it is in the right position it will tend to increase in size. Arthroplasties are not good operations in children or even in adolescents. With the Smith-Petersen cup, of course, the whole question of arthroplasties is going to have to be reconsidered. We won't know the answer for some years. It is possible that later on by means of this new principle it may be possible to get satisfactory results in children. I have not had satisfactory results in arthroplasty of the hip in adults. I have not done them except in bilateral cases. I do not like the index of function based on the movement of the hip. The least important quality of the hip is movement. The most important quality of the hip is stability, the next is absence of pain, and finally comes the question of movement. I was struck by the fact that Dr. Hallock considers the straight position the ideal position. We are gradually getting away from the old idea that we want our hips abducted when we do an arthrodesis and are immobilizing our hips nearly in the straight position. I am pleased to have Dr. Hallock advise early operation in acute pyogenic infection of the hip. There is a great tendency to let the patient battle with the disease and then drain the abscess after an equilibrium has been established between the patient's resistance and the virulence of the organism. I believe that with an acute pyogenic infection of the hip joint it is better to operate early when one suspects the disease than it is to wait until one is sure that the disease is there and the joint is destroyed. It must not be forgotten, either, that we have all seen patients die of pyogenic infection who have not been operated on.

DR. FRANK D. DICKSON, Kansas City, Mo.: The problem of restoring to satisfactory use a hip joint damaged in childhood or adolescence by suppurative arthritis is a very complex one. This is demonstrated by the fact that four different procedures were carried out for this purpose at the New York Orthopaedic Hospital. In the hip joint instability and deformity are responsible for most of the disability, and these two factors must be overcome if a satisfactory weight bearing extremity is to be anticipated. The preservation of a useful amount of motion in the hip joint is highly desirable, and in bilateral involvement imperative but sacrificing stability and satisfactory alignment in favor of limited and often unusable motion is never wise. The series reported by Dr. Hallock indicates that, while many excellent results were obtained by arthroplasty and shelf operations, by far the most satisfactory cases in the series are those in which an arthrodesis was performed, the reason being that, by arthrodesis, stability was provided and a proper alignment secured, so that weight bearing could be satisfactorily carried out. My experience with reconstruction operations and shelf operations in hip joints damaged by suppurative arthritis parallels that reported by Dr. Hallock. The unreliability of the results in plastic operations has convinced me that, in the management of such joints, fusion is by far the most dependable operation. Attempts to preserve motion in a hip joint damaged by suppurative arthritis often interfere with the primary objective of securing stability and satisfactory alignment. Procedures aimed at securing a movable hip joint should be reserved for selected cases. The obstacles to success in the usual case are four: 1. Most of these hips are in a position of pathologic dislocation and show a marked tendency to return to this position after operation. 2. The extensive destruction which is usually present leaves but little head and neck for reconstructive surgery. 3. The extensive fibrosis of the periarticular structures present usually reproduces itself after operation, often to a greater extent than before, and interferes with the establishment of satisfactory motion. 4. It is difficult to build up muscle control of the joint, owing to atrophy and fibrosis of the muscles which control the movements of the joint. There is perhaps something more encouraging in the future.

DR. EDWIN W. RYERSON, Chicago: Many of these suppurative arthritides occur in early infancy. They used to be called the acute epiphysitis of infancy. In many of the cases which

I have seen the entire head and neck were absorbed and disappeared and there was nothing left but the straight shaft with the trochanter playing up and down on the side of the ilium, producing a great deal of instability and but little pain. A good deal of shortening occurs in such cases, and years ago, soon after Lorenz's bifurcation operation was brought out, I began doing a high Lorenz bifurcation of the upper end of the femur, and the results were highly satisfactory because good stability and good motion were attained. It has recently seemed possible that the Colonna operation of denuding the upper end of the greater trochanter from its muscle attachments and placing the upper end of the trochanter in the acetabulum might produce more lengthening than is obtained by the other methods, and a good deal of motion. I am greatly in favor of having some motion in the hip joint if one can possibly get it when it can be combined with stability and painlessness. So I am willing to take chances on making painless and movable hip joints in individuals of reasonable age, because one can always perform an arthrodesis of the hip joint as a last resort. I appreciate Dr. Hallock's paper and I think it covers an important field, although nowadays one does not seem to observe so many cases of suppurative arthritis as were seen fifteen or twenty years ago.

SOME PECULIARITIES IN THE GEOGRAPHY OF CANCER

JOSEPH W. MOUNTIN, M.D.

AND

HAROLD F. DORN

Senior Surgeon and Statistician, Respectively, United States
Public Health Service

WASHINGTON, D. C.

In discussions of the relationship of climate and geography to health, attention has been especially directed toward communicable diseases. This perhaps is to be expected, since these are the diseases against which most control measures have been directed. Geographic variations in the prevalence of conditions due to other

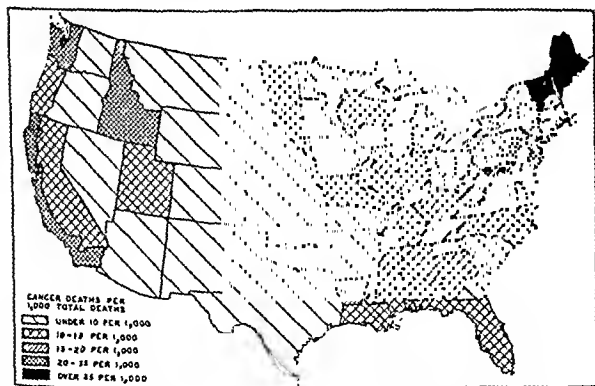

Fig. 1.—Number of deaths from cancer per thousand deaths from known cause, 1880.

possible factors, however, have not been overlooked. Of particular interest with respect to cancer is the fact that Dr. John S. Billings pointed out the wide geographic variation in cancer mortality as revealed by the United States Census of 1880 (fig. 1). Although the data were admittedly incomplete, they indicated that cancer most frequently occurred among persons living

in the states extending from New England to the Great Lakes and in the Pacific Coast states.¹

Among the items taken up for study by the United States Public Health Service after the passage of the National Cancer Institute Act of 1937 was the distribution of cancer in the population. Two sources of data were used: certificates of death and reports of cases under treatment. Partial figures presented on this occa-

Fig. 2.—Number of deaths from cancer per hundred thousand of total population by states, 1937.

sion are taken from more extensive material.² The term "cancer" as used in this paper includes new growths of all types having inherent malignant characteristics. Mortality data will be presented first. These were obtained from basic tabulations of the Vital Statistics Section of the Census Bureau, which show greater detail than the annual reports on mortality statistics.

Crude death rates from cancer vary widely throughout the country (fig. 2). The extreme situations may be cited to illustrate this point. In Rhode Island, 156 persons per hundred thousand of total population died of cancer during 1937, as contrasted with the corresponding rate of fifty-two for South Carolina. In other words, three times as many people, in relation to the total population, succumbed to cancer annually in the state of highest as compared with the one of lowest experience.

Although these two states have been singled out as representing the extremes, differences only slightly less in magnitude exist among other states and groups of states. The experience of New York and of New England is between two and three times that which obtains in the South. The states around the Great Lakes and bordering the Pacific Ocean also have rates well above the average for the entire country.

Certain obvious explanations for these variations immediately come to mind, and no doubt these are operative in some degree. Aside from a few notable exceptions, states with the highest rates have populations that are largely urban; consequently they may be expected to have available superior facilities for diagnosis. Moreover, the states with the lowest death rates from cancer are also states where an appreciable proportion of the deaths are certified as being due to senility and other vague or ill defined causes. If

2. Cover, Mary: The Trend in Cancer Mortality, Original Registration States 1900-1936, Public Health Bulletin, to be published; Distribution of Cancer Mortality in Continental United States, 1936, *ibid.*, to be published. Mountin, Joseph W.; Dorn, Harold F., and Boone, Bert R.: The Incidence of Cancer in Atlanta, Georgia, and in Surrounding Counties, Pub. Health Rep. 54:1255 (July 14) 1939; similar data for other areas, to be published.

more specific diagnoses were obtained, it is possible that some of these deaths from indefinite causes would be attributed to cancer, although the larger number probably result from diseases of the heart and arteries, disorders of the kidney and other common ailments of the aged. It is not believed that varying degrees in specificity and accuracy of diagnosis would account

Fig. 3.—Standardized death rate from cancer per hundred thousand of population, 1937.

for more than a small percentage of differences in mortality rates.

A more important factor likely to affect the crude death rate is the diversity in the composition of the population among the states. The usual method of taking account of differences in the composition of the population is to adjust rates to a standard population.³ It may be appropriate to add a word of caution, to the effect that adjusting for age and race reduces the geographic variation in mortality but does not entirely

Fig. 4.—Average annual death rate per hundred thousand of population from cancer of the buccal cavity, respiratory system and skin by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

eliminate it. Since the mortality from cancer is less among Negroes than among white persons, the standardized rates for the Southern states are based on the white population only.⁴ Rates standardized for age are shown in figure 3.

3. The standard population used is the population of the United States in 1930.
4. The rates refer to the white population in Alabama, Arkansas, California, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee and Virginia.

After age adjustments have been made, the resulting standardized rates in New York and Rhode Island are still twice those in Arkansas and New Mexico, with the general pattern of geographic variation remaining similar to that for the crude rate. It is interesting to note that Louisiana and Florida each occupies a position more than 25 per cent above that in the other Southern states. This may be no more than a coincidence for Florida, a state southern only by location since half of its population were born outside the state; but the data in respect to Louisiana may have significance, as more than 85 per cent of the inhabitants are native to that state.

Mortality from cancer by anatomic sites and by geographic regions is shown in figures 4 to 9. Figures 4 and 5 present data for groups of sites, while figures 6 to 9 show corresponding data for individual sites. These rates also have been adjusted for differences in age composition. Directly opposite to the distribution

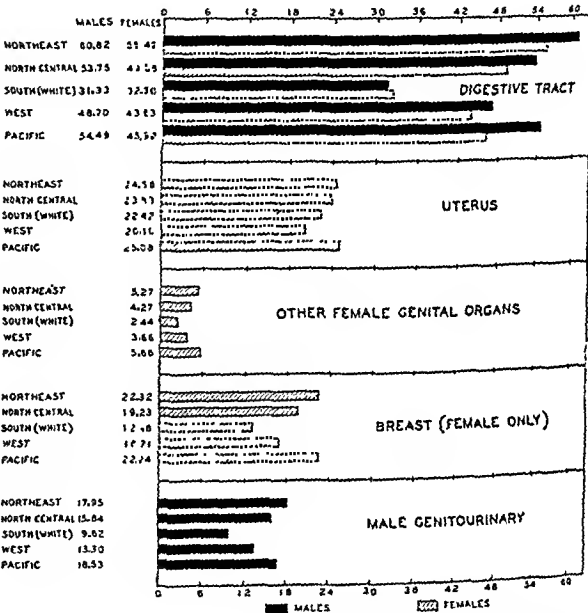

Fig. 5.—Average annual death rate per hundred thousand of population from cancer of certain selected sites by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

of total cancer mortality is that of the skin alone. Lesions of this site claim proportionately more victims, both male and female, in the South as compared with the remainder of the country, but among other regions the difference is of little moment (fig. 4). It has been suggested by some that the higher mortality in the Southern states may result from greater exposure to the sun. However, the Western states, many of which also have a very hot season and relatively more clear weather throughout the year, report the lowest mortality from skin cancer.

Lesions of the buccal cavity show an interesting sex difference in the geographic variation picture. The mortality among males follows the pattern for all cancer, being highest in the Northeast and lowest in the South

5. The states in the five regions are as follows: Northeast: Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, District of Columbia. North Central: West Virginia, Ohio, Indiana, Illinois, Michigan, Wisconsin, Minnesota, Iowa, Missouri. South: Virginia, North Carolina, South Carolina, Georgia, Florida, Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Oklahoma, Louisiana. West: North Dakota, South Dakota, Nebraska, Kansas, Montana, Idaho, Utah, Wyoming, Nevada, Colorado, Arizona, New Mexico. Pacific: Washington, Oregon, California.

and West. For females, however, rates are highest in the South, lowest in the West and practically equal in the other regions. The cause of this difference is not apparent. From the standpoint of magnitude, the difference is most pronounced for cancer of the pharynx and mouth although some inequality obtains for each specific site (fig. 6).

While mortality from cancer of the pharynx and mouth is especially high among Southern white females as compared with those of other regions, a high rate is also characteristic of Southern white males. The same statement, however, does not apply to cancer of the tongue, which is less frequent among Southern white males than among males in the Northeast, North Central and Pacific states. Mortality from cancer of the lip shows little geographic variation except for the South, where it is low for males and high for females (fig. 6).

Mortality from cancer of the uterus presents a situation dissimilar from that of other sites in that there

Fig. 6.—Average annual death rate per hundred thousand of population from cancer of the tongue, pharynx, lip and mouth by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

is almost no geographic variation (fig. 5). In contradistinction, the death rate from cancer of the other female genital organs follows the usual geographic pattern. Statements somewhat similar to the latter may be made in respect to cancer of the male genito-urinary system, digestive tract and breast.

Nothing especially important from a geographic standpoint was revealed by the study in regard to malignant conditions of the larynx, lungs and other respiratory organs (fig. 7).

Prostatic malignant change produces a rate that is more than 50 per cent higher in the rest of the country than it is in the South (fig. 8). From this aspect it is similar to mortality from cancer of the kidneys but different from cancer of the bladder, which is highest in the Northeast, North Central and Pacific regions but lowest in the South and West.

Except for the South, cancer of the stomach is universally the most common form of fatal cancer among males, ranking with cancer of the breast and uterus

among females (fig. 9). Much the same picture is presented by mortality from cancer of the liver, except that the Pacific Coast states also constitute an area of relatively low rate. The geographic distribution of fatal cancer of the intestines and other parts of the digestive tract is very similar to that already described for all forms of cancer combined.

Fig. 7.—Average annual death rate per hundred thousand of population from cancer of the lungs and larynx by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

It is well known that some forms of cancer pursue a more rapid and fatal course than others. For example, cancer of the stomach usually terminates in death shortly after diagnosis, while a person may live for many years and perhaps die of another cause should the skin only be involved. Conclusions, therefore, based on mortality records will differ from those drawn from morbidity reports not only as to the amount of cancer in the population but also in respect to the tissues or organs involved. Furthermore, as therapeutic methods become more effective, the types of cancer most easily arrested will appear less and less frequently in mortality records.

Fig. 8.—Average annual death rate per hundred thousand of population from cancer of the prostate, bladder and kidney by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

Because of these considerations, a number of studies have been initiated by the United States Public Health Service in representative sections to determine the morbidity from cancer and its variation from one part of the country to another, between the two sexes, between white persons and Negroes and at different ages. Field methods used are described in another paper of the cancer statistics series, but it may be well to repeat that the data are obtained directly from physi-

cians, hospitals and clinics and cover patients seen within a specified year (Mountin, Dorn and Boone²). Individuals are sufficiently identified to exclude factors of error that might be introduced by residence and duplication of reports.

The several areas chosen for the complete study give representation to the main geographic divisions of the continental United States. Preliminary data for total

Fig. 9.—Average annual death rate per hundred thousand of population from cancer of the stomach, intestines and rectum by sex in the United States excluding Texas, 1930-1932 (adjusted for differences in age distribution).

cancer have been tabulated for areas⁶ centering around Atlanta, Chicago, Detroit, Pittsburgh and New Orleans; these are presented in figure 10. Considerable variation in case rates for cities of the same region may be noted, but the difference between Northern and Southern cities is impressive. The case rates of illness, unlike the mortality rates, are higher in the South than in the North, those for the Southern area being about one-third higher than the rates in the Northern area. Expressed as a ratio of cases to deaths, the incidence of cancer ranges from 2.6 in Chicago to 5.3 in Atlanta.

The more detailed analysis by site has been completed on information from the Atlanta and the Chicago areas. On this occasion bodies of data from Atlanta and Chicago are used to illustrate geographic differ-

Fig. 10.—Number of cases of cancer per hundred thousand of total population for selected cities, 1937.

ences in the incidence of cancer and to show how figures based on morbidity reports vary from those derived from recorded deaths. When interpreting the figures hereinafter presented, one should remember that regardless of how the incidence of cancer is expressed—whether as the number of cases per death or, as the number of cases per unit of population—the estimated figure will depend in great measure on the accuracy

6. The Atlanta area includes the following counties of Georgia: Cherokee, Clayton, Cobb, DeKalb, Douglas, Fayette, Forsythe, Fulton, and Barnett. Cook County, Ill.; Wayne County, Mich.; Allegheny County, Pa., and Orleans Parish, La., comprise the areas respectively designated as Chicago, Detroit, Pittsburgh and New Orleans.

of diagnosis, the effectiveness of therapeutic methods, and the stage at which the disease is recognized. In any survey of the type described certain cases are missed because of faulty diagnosis or because of their not having come to medical attention, but for all practical purposes it is not possible to obtain information on other than cases of diagnosed cancer. As a consequence, the number of cases of cancer referred to in this paper really represents the number of unduplicated persons with diagnosed cancer who came to the attention of a physician, hospital or clinic during the calendar year previous to the survey.

In a community where a high proportion of diagnoses are unduly delayed, the recorded number of cases may be only slightly greater than the recorded number of deaths. For example, if each patient lives just one year after a positive diagnosis, the case rate in any given year will be equal to the mortality rate of the following year. On the other hand, if each person with

Fig. 11.—Percentage of reported cases of cancer by primary site and sex for white persons in Atlanta, Ga., and Chicago, 1937.

cancer should live, on the average, five years after diagnosis, the incidence rate at any time will be five times the mortality rate five years later. While the effect of delayed diagnosis cannot be entirely eliminated, an attempt has been made to minimize its influence by undertaking the study only in areas having superior medical, hospital and clinical facilities that are reasonably accessible to all groups of the population.

The higher case rates of illness from cancer in the South arise, in part at least, from a higher incidence of skin cancer (fig. 11). Nearly two of every five cases of cancer among white males reported in Atlanta affected skin as compared with one of eight in Chicago. For white females the proportions, although smaller, show about the same relative difference, 23 per cent in Atlanta and 7 per cent in Chicago. Similarly cancer of the lip in relation to all forms was reported twice as frequently for white males and four times as frequently for white females in Atlanta as compared with Chicago. These two types of lesions made up 57 per cent of all cancers among white males and 24 per cent

of all cancers among white females in Atlanta but only 27 per cent and 7 per cent, respectively, in Chicago.

On the other hand, the digestive tract and the respiratory system were reported as sites more frequently in Chicago than in Atlanta, the corresponding percentages being 45 for white males and 23 for white females in Chicago as compared with 16 for white males and 10 for white females in Atlanta.

Fig. 12.—Percentage distribution by primary site and sex of reported cases and recorded deaths from cancer in Atlanta, Ga., and surrounding counties, 1937. (The deaths are for the state of Georgia.)

For specified sites the occurrence of cancer varied markedly when measured by morbidity as compared with mortality reports (figs. 12 and 13). In some measure this may arise from the fact that tumors of one type are more malignant than those of another or because of varying susceptibility to treatment. In Atlanta cancer of the skin, to which is attributed 37 per cent of all cases among males and 20 per cent among females, accounts for only 6 per cent of the male deaths and 3 per cent of the deaths among females. On the other hand, malignant tumor of the digestive tract, which causes nearly 50 per cent and 30 per cent, respectively, of all male and female deaths from cancer, is reported about one-fourth as frequently among cancers in living patients for this locality.

In Chicago the same general relationships between cancer in dead and in living patients hold true, although the proportions are quite different. Cancer of the digestive tract is reported as the primary site for 55 per cent of the fatal tumors but for 35 per cent of the tumors in living patients among males; the corresponding figures for females are 42 and 20, respectively. The rectum and anus are the only tumor sites in the digestive tract reported as frequently among tumors in living as among those in dead patients.

No attempt has been made in this paper to do more than point out the existence of geographic variations in the occurrence of cancer. That such variations exist, there can be no doubt. The explanation of these differences must await further investigation into the causes of cancer. However, the existence of significant

differences not only in the total amount of cancer but also in the types of lesions indicates that contributory factors, perhaps multiple and varied, may be found in the environment.

ABSTRACT OF DISCUSSION

E. V. COWDRY, PH.D., St. Louis: This paper is a concise report on the beginning of a systematic, large scale analysis of the factors for and against cancer. To distinguish the geographic ones from the others is difficult. The authors have mentioned corrections for age and for standardized population and I hope that they will explain these corrections a little further. There is also the possible factor of race. In the North both white persons and Negroes appear to have been included in these statistics, while in the South the Negroes were not taken into consideration. On the whole it is possible when the groups studied in different parts of the country are selected on the basis of similarity in age, race, economic status and other factors that the striking differences in cancer incidence described will be reduced.

DR. J. N. BAKER, Montgomery, Ala.: The data accumulated by the Public Health Service under the direction of Dr. Mountin seem to confirm amply the frequently observed fact noted by Southern clinicians that there is considerable predominance of cancer of the skin among the white population of the South, which predominance is even more marked in the rural portion of its population. On the other hand, the Negro, whose body is probably even more exposed to the sun's rays, appears to be nothing like so susceptible to the development of cutaneous cancers. His skin pigmentation, no doubt, is accountable at

Fig. 13.—Percentage distribution by primary site and sex of reported cases and recorded deaths from cancer in Cook County, Ill., 1937.

least in part for such immunity. Such a thoroughgoing, comprehensive study in the cancer field is badly needed and, when completed, should place at our disposal a wealth of useful information.

DR. FREDERICK G. MURRAY, Cedar Rapids, Iowa: This study of the geographic distribution of cancer is most interesting. One point about bright sunlight and the prevalence of skin cancer is the matter of exposure. The incidence of cutaneous cancer in southern California is considerably less than in other Southern states. There is the same brilliant sunlight in southern California as in other parts of the South; the low incidence

of cutaneous cancer in California may be due to the comparative lack of exposure of the white population there to the sunlight. In California the rural outdoor work is done almost exclusively by the Oriental and Mexican laborer, whose pigmented skin protects him from the effects of sunlight. In the other Southern states a much larger proportion of the white population engages in outdoor field labor and is correspondingly more exposed to sunlight, thus accounting for the greater prevalence of cutaneous cancer in these other Southern states.

DR. JOHN A. FERRELL, New York: I wish to inquire if this paper is to be the first of a series, so that later factors will be treated that were not discussed here. It is presumed that comparisons of groups by age will be made. Might not the recognized high average age of the population in New England and California account in part for their high cancer mortality? Is not the cancer rate notably high in particular racial groups? Does not occupation exert an influence on rate? In computing cancer rates, I wonder how the authors arrived at their population basis. If the 1930 census is employed, considerable change may have occurred in certain communities during the past nine years and might account for some variation.

DR. A. G. HENDERSON, Imboden, Ark.: I have two questions to ask: Has cancer increased greater in the last twenty years than the population of the United States? What effect has the treatment of cancer had in reducing the mortality in the last twenty years?

DR. JOSEPH W. MOUNTIN, Washington, D. C.: To answer many of the questions raised in the discussion would require data of a different type than those on which this study was based. Our data were limited to a few items such as residence, age and sex of the patient and site of the cancer. These were obtained through mortality records and a special incidence survey. With but few exceptions each report of cancer used represents a diagnosis by a physician. For administrative reasons it was necessary to limit the number of questions asked. I may add, however, that the Public Health Service now has in progress an epidemiologic study of cancer involving the collection of data much more detailed in character than those described. This epidemiologic study is being done in connection with several well organized cancer clinics. Its primary purpose is to determine the significance that may be attached to the various clues advanced by clinicians as to factors associated with the occurrence of cancer. No figures on cancer among Negroes were used in the paper we have presented. Such exclusion was necessary to insure comparability between geographic areas. For the incidence portion of our study, figures were gathered from certain large cities in each of several geographic regions. Extending the study to rural areas would have entailed very high costs; furthermore, differences between large medical centers and rural areas in the availability and use of good diagnostic service probably would have invalidated any direct comparison between the cancer experience of urban and rural inhabitants. The factor of occupation in connection with cancer could not be assayed on the basis of data used for this paper. This, however, is being attempted in the epidemiologic study which I have mentioned. The factor of age was taken into account by the usual method of computing standardized rates for each state on the basis of the age distribution of the population of the United States in 1930. Cancer mortality is on the increase. The part of this increase that is due to changing age composition of the population can be estimated. Improvement in diagnosis is another factor but its effect varies with the character of local facilities and the site of the cancer.

DR. FERRELL: Did you take the occupational factor into consideration?

DR. MOUNTIN: No. We had to choose between what we could get and what we would like to get. We made our questionnaire. We sent it around. If it had been too extensive we should have had difficulty in getting it filled out and, furthermore, occupation is a difficult thing to classify. You have to get down much beyond the mere gross classification of population and get into exposure to different irritants and other factors that might have something to do with the causation of cancer. We are doing that in our epidemiologic study, but those data are not in the incidence study on which we have just reported.

Clinical Notes, Suggestions and New Instruments

CHEILITIS, FIXED DRUG ERUPTION AND GASTRO-INTESTINAL ALLERGY FROM EOSIN DYE OF LIPSTICK

RUDOLPH HECHT, M.D.; B. Z. RAFFAPORT, M.D., AND
LEON BLOCH, M.D., CHICAGO

Mrs. P. W. W., aged 43, white, was referred to us in March 1936. She complained of itching eyelids, scaling and redness of the skin about the eyes and an eruption at the corner of one eye. The symptoms began in August 1934. The itching had persisted since then with exacerbations and remissions. A physician advised the use of "nonallergic" cosmetics and prescribed solution of potassium arsenite and calcium. She did not improve on this regimen; in fact, her skin became more irritated. One of us (L. B.) diagnosed gastrointestinal allergy in 1935, the symptoms of which were frequent bowel movements (composed largely of mucus), cramps and pencil-like stools. The physical and laboratory examinations at that time revealed no abnormalities. The information obtained during her first visit was that she was using perfumes, toilet waters, talcums, face powder, various creams, liquid nail polish, "henna," rouge and lipstick. On examination the following was noted: The skin of the face showed generalized erythema. On the area adjoining the outer side of the left eye there was a slightly elevated, roughly triangular, peanut sized, lichenified plaque, of dusky red violaceous color, which was sharply demarcated from the surrounding skin. The skin in back of both ears was erythematous and scaling, while the lips were dry, fissured and scaling. There was moderate dry scaling of the scalp.

At the first visit cosmetics were suspected. Therefore the patient was advised to discontinue the use of all cosmetics. Intracutaneous tests were made with all the common foods in an attempt primarily to discover the cause of the gastrointestinal symptoms. These tests all gave negative results except for a questionable reaction to banana, which clinically proved to be of no significance.

After avoidance of cosmetics for one week it was noted that the redness of the face had subsided and that the skin behind the ears was now completely clear. Also, to our surprise, the abdominal distress had completely subsided. At this visit she begged to be allowed "at least the use of lipstick," since she was unable to go among her friends "looking like a ghost." Two days after the resumption of the use of lipstick the eruption at the corner of the eye and the abdominal distress reappeared. Patch tests were then made with all the cosmetics that had been used. The lipstick gave a 4 plus reaction with erythema, edema and severe vesiculation. In order to explain why no improvement had occurred when the "nonallergic" cosmetics had been used, a patch test was made with the "nonallergic" lipstick. This also gave a 4 plus reaction. Samples of the constituents of this lipstick were obtained from the manufacturer and were used for patch tests. All were negative except for brom acid (tetrabromofluorescein), which gave a 4 plus reaction. The old sites of patch test reactions flared up after this reaction.¹ Erythema of the face in the areas of the previous cutaneous eruption occurred with the positive cutaneous reaction on the arm.

Various bromofluoresceins and other dyes commonly used in lipsticks were supplied to us by the Ar-Ex Cosmetic Company, Inc. Patch tests with these dyes were negative except for the tetrabromofluoresceins. A lipstick prepared by this company containing no "indelible" dye was negative on patch test. The patient has for the past three years used "nonindelible" lip rouge and has resumed the use of all other cosmetics and perfumes with no recurrence of the cutaneous or gastrointestinal symptoms. No dietary restriction has been necessary. The disappearance of the gastrointestinal symptoms was particularly

From the Department of Physiological Chemistry, University of Illinois College of Medicine, and Michael Reese Hospital.
1. Stauffer, H.: Die Ekzem Proben, Arch. f. Dermat. u. Syph. 162: 517, 1931.

interesting. During the past three years we have attempted several times to induce her to try the ingestion of capsules containing a small amount of tetrabromofluorescein. We were interested in knowing whether the gastrointestinal symptoms and the eruption would return. She has, however, refused to swallow any of the dye, preferring to "let well enough alone."

The interesting facts indicated by this study are the presence of cheilitis, a patch of dermatitis of the "fixed" type and of gastrointestinal symptoms. The elimination of the bromofluorescein dye from the lipstick resulted in the disappearance of the symptoms. There has been no recurrence for the past three years. We believe it is probable that the cheilitis was a contact dermatitis due to the tetrabromofluorescein dye in the lipstick. That these dyes can cause this type of dermatitis is well known. The role of this substance as an etiologic factor in lipstick dermatitis has been thoroughly studied by Sulzberger and Goodman.² That it was the causative factor in our case was proved by:

1. Positive patch test with the lipstick.
2. Positive patch test with the tetrabromofluorescein used in the manufacture of the lipstick.
3. Negative patch tests with the other ingredients of the lipstick.
4. Improvement of symptoms when the use of lipstick was stopped.
5. Return of symptoms when the lipstick was again used.
6. Negative patch tests with a lipstick free from tetrabromofluorescein.
7. Complete clinical relief for a period of three years after substitution of such a lip rouge.

The peculiar patch of dermatitis near the eye was not characteristic of a contact type dermatitis, although the dye could have been carried there by the fingers. However, if this lesion near the eye was the result of dye carried there by this means it is difficult to understand why the eruption was limited to such a small area rather than involving the eyelids, which are more commonly affected by such contact. It is possible that this site was an area of local sensitization. Since this patch was sharply circumscribed, did not contain vesicles, was violaceous, disappeared on removal of the offending agent from the lips and reappeared when the lipstick was reapplied to the lips, it may possibly have been a lesion of the fixed drug eruption type due to the ingestion of the eosin dye.

We know of no reported case of such an eruption due to this dye. Unfortunately we were unable to feed the dye and observe the effects. Sulzberger and Wise,³ Abramowitz⁴ and Abramowitz and Noun⁵ have thoroughly studied fixed drug eruptions due to phenolphthalein. Similar eruptions have been reported due to antipyrine, allurate and arsphenamine.

The gastrointestinal symptoms were especially interesting and may be of importance in explaining other obscure cases of vague gastrointestinal symptoms frequently complained of by women.

Various substances of relatively simple structure (i. e. not proteins) are capable of causing gastrointestinal allergic symptoms.⁶ It is possible that these substances act as haptens and take on the character of full antigens by union with body proteins, as suggested by Wolff Eisner in 1907. In fact, the recent work of Rosenthal⁷ with phenolphthalein in which he believes he has demonstrated *in vivo* union of hapten to protein may be significant in this regard.

SUMMARY

This case of contact dermatitis, possible "fixed drug" eruption and gastrointestinal allergy was due to tetrabromofluorescein in a lipstick.

The general use of lipsticks containing tetrabromofluorescein or related dyes by American women may explain many obscure cutaneous eruptions, especially of the "fixed" type, and may explain some cases of gastrointestinal disturbances of the nature of spastic colitis or mucous colitis.

RESISTANCE TO PROTAMINE ZINC INSULIN WITHOUT
RESISTANCE TO REGULAR INSULIN IN
DIABETES MELLITUS

JAMES A. GREENE, M.D., AND O. D. THATCHER, M.D.
IOWA CITY

Temporary resistance to insulin in diabetes mellitus is not an uncommon occurrence, but resistance to one type of insulin without resistance to another is rare. It is for this reason that we are reporting a case in which there was resistance to protamine zinc insulin and not to regular insulin.

REPORT OF CASE

A white woman aged 27, single, entered the University Hospital Aug. 3, 1938, because of an acute inflammation of the left external ear and diabetic acidosis. Diabetes mellitus had been present for eleven years and had been treated haphazardly with insulin and modifications of the diet. Growth ceased shortly after the appearance of the diabetes, and the secondary sex characteristics did not develop nor did menstruation occur. For six months prior to admission the diabetes became more severe and was not adequately controlled, although more vigorous treatment was instituted. A furuncle developed in the left

* Carbon dioxide combining power 26 volumes per cent.

external auditory canal three days before admission, and the infection spread to the auricle. The patient lapsed into coma and was sent to the hospital immediately.

The patient was small, thin and underdeveloped and appeared to be about 16 years of age. She was in a semicomatose condition. The left external ear was acutely inflamed, with pus exuding from the canal. Large amounts of dextrose and acetone were in the urine. The blood sugar concentration was 367 mg. per hundred cubic centimeters and the carbon dioxide combining power was 17 volumes per cent.

The acidosis was controlled by the administration of dextrose and regular insulin. The infection subsided after incision of the left auricle. The diabetes was finally controlled with insulin in doses of 5 units at midnight, 25 units before breakfast, 10 units at noon and 20 units before supper, and a diet of three meals daily containing 170 Gm. of potential dextrose.

From the Department of Internal Medicine, State University of Iowa College of Medicine.

Elimination of the midnight dose of insulin or alteration of the time of administration resulted in moderate to extreme glycosuria. The regimen was changed, therefore, to four meals daily, at 7 a. m., 11:30 a. m., 5 p. m. and 10 p. m. Insulin was administered before each meal in doses of 25, 5, 15 and 15 units. The glycosuria was controlled for approximately two weeks before protamine zinc insulin was substituted for regular insulin. It is to be noted from the table, which shows the doses of insulin, potential intake of dextrose and amount of glycosuria, that the protamine zinc insulin was ineffective and that acidosis developed. The return to regular insulin in the previous doses promptly controlled the glycosuria by the third day. Another attempt (twenty-eight days later) to use protamine zinc insulin in daily doses of 90 units resulted in a glycosuria of from 30 to 33 Gm. daily. This glycosuria subsided when regular insulin was again administered. Positive reactions followed the intradermal injections of protamine zinc insulin in this patient, whereas negative reactions were obtained in other diabetic patients; also this patient failed to react to regular insulin thus administered.

COMMENT

We have been able to find only one report in the literature of resistance to protamine zinc insulin without resistance to regular insulin. John's¹ patient had hemochromatosis, but there was no evidence of this malady in our case. The cause of such resistance is not clear. That the protamine zinc insulin was active was shown by the fact that another patient received insulin from the same vials and her diabetes was controlled. The protamine zinc insulin appeared to be absorbed, as evidenced by the absence of masses beneath the skin at the sites of injection. It is generally believed that protamine zinc insulin is retained at the site of injection, and this is supported by the observations of Allen.² It appeared probable, however, that the protamine zinc insulin was transported to some other site in the body in our patient and some may have been excreted by the kidney. It is for this reason that several twenty-four hour specimens of urine were examined for protamine and for insulin, but neither was demonstrable in any of the specimens. The failure to liberate the insulin in our patient may have been due to the allergic reaction which altered the protamine and thereby prevented it from being broken down in the usual manner. The positive reaction to intradermal injections of protamine zinc insulin in our patient would support such a contention.

SCIATIC NERVE PRESSURE FOLLOWING RUPTURE AND FIBROSIS OF A HAMSTRING MUSCLE

P. M. GIRARD, M.D., DALLAS, TEXAS

AND

H. M. CHILDRESS, M.D., JAMESTOWN, N. Y.

This case is reported because no similar case could be found in the literature and because of the exceptional symptoms from a known condition, the failure of the usual surgical repair of a ruptured muscle to relieve symptoms and the excellent result from a final radical procedure.

REPORT OF CASE

A college student aged 21 sustained a traumatic injury to the distal posterior part of the left thigh in football practice in late October 1936. He was indefinite about the exact manner of his receiving the injury as he was beneath a pile-up of players. The traumatized area was treated with radiant heat and light massage for several days. He had pain on walking for the next few weeks but after that he had no trouble in the injured extremity until he entered spring football practice. At that time motions of the left knee seemed difficult to initiate and he had moderate weakness in the entire leg. Also a bulging mass developed in the midline of the posterior part of the thigh about 10 cm. above the superior boundary of the popliteal space. This tumor seemed to be of fibrous tissue, was moderately tender on pressure and was visible and palpable only when the knee was in flexion.

On examination a diagnosis was made of partial or complete rupture of a medial hamstring muscle with fibrosis due to continued use following injury. Through a longitudinal incision the hamstring muscles were exposed in the distal half of the thigh. The semitendinosus muscle was found to have an old partial rupture about 8 cm. above the musculotendinous junction. A mass of tissue, which appeared to be fibrous, filled the gap in the muscle. The tumor was excised, the muscle fibers were brought snugly together with No. 2 chromic interrupted sutures, and the wound was closed in layers. Motion was started at the knee in ten days and full activity was permitted at the end of four weeks.

The patient played football during the autumn of 1937 but was not able to handle the left extremity in a normal manner. He complained of weakness in the knee and inability to make sudden movements at this joint. Late in the season, while doing short practice sprints before a game, he felt a tearing sensation at the operative site. He had marked pain and was forced to walk with crutches for several weeks. He then discovered he had a small mass, moderately tender to pressure, in the lower posterior part of the thigh similar to the one present prior to the muscle repair.

In October 1938 he began work as a linesman with a telephone company. His duties included climbing and remaining on poles for long periods. At this time he began having unusual symptoms in the left leg. After being on a pole for twenty to thirty minutes he would develop a partial paralysis of the left ankle and anesthesia over the lateral and posterior portions of the leg and of the entire foot. When he returned to the ground both the motor and sensory disturbances would disappear immediately on his massaging the leg and passively moving the ankle. These symptoms of sciatic nerve pressure, he noticed, occurred only when the knee was kept in continuous hyperextension for periods longer than fifteen minutes.

He was examined again in late autumn. At that time a definite mass 6 by 4 by 1.5 cm. would appear in the midline of the distal posterior portion of the left thigh on flexion of the knee. There was but slight pressure tenderness. Results of neurologic examination were negative. No pathologic change of bone or joint was demonstrable by roentgenograms. It was believed that the motor and sensory changes of which the patient complained were due to localized fibrosis of the semitendinosus muscle which pressed on the sciatic nerve when the knee was in hyperextension. In such a position the tightened posterior fascia would force the mass laterally and anteriorly against the sciatic nerve. Surgical exploration was advised.

Exposure of the semitendinosus muscle showed a thickened muscle belly about 10 cm. proximal to the musculotendinous junction. The muscle appeared to be under normal tension but the fibers seemed coarser than normal. Since the patient had requested general anesthesia it was impossible to reproduce the exact swelling noted clinically. The tendon of the muscle was released at its insertion and the muscle was excised near its origin. The sciatic nerve was not explored. Motion was started at the knee in ten days and full unprotected activity allowed in six weeks.

Schematic drawing of the posterior part of the thigh, showing localized fibrosis of the semitendinosus muscle and its relation to the sciatic nerve.

1. John, H. J.: Hemochromatosis Without Pigmentation of Skin: Resistance to Protamine Zinc Insulin. *J. A. M. A.* 112:2272-2273 (June 3) 1939.

2. Allen, F. M.: Tolerance and Toxicity of Insulin: III. Protamine and Zinc Compounds. *Ann. Int. Med.* 12:1870-1885 (May) 1939.

The specimen of tissue examined consisted of the semitendinosus muscle with the attached tendon. The lower third of the muscle, on section, was grayish white and increased in consistency. In some areas strands of firm fibrous tissue almost completely replaced the normal tissue.

Microscopic study showed a large amount of rather dense fibrous stroma which contained numerous small thin-walled blood vessels. In areas this fibrous tissue stroma was so diffuse that only small individual muscle fibers were seen. There was atrophy of the muscle fibers, shown by the loss of staining character, and there was slight breaking up of the nucleus with vacuolation of the cell cytoplasm.

The pathologic diagnosis was extensive fibrosis of the semitendinosus muscle caused by trauma.

The patient has been seen every two or three weeks and has had no recurrence of the nerve pressure symptoms. Motions at the knee are now unrestricted and painless, and the circumference of the left thigh measured 15 cm. above the patella is but 2.5 cm. less than that of the normal right thigh. The power of the left hamstring muscles is now (five months after operation) about 80 per cent normal. The patient walks without a limp and states that he is able to use the knee more efficiently than before the muscle resection.

COMMENT

Conwell and Allredge,¹ Gilcreest² and McMaster³ have made extensive studies on tears and ruptures of muscles and tendons. Gilcreest^{2c} reported rupture of the semitendinosus muscle of a man 59 years of age. This patient fell to the ground while lifting some heavy lumber and struck on his left thigh posteriorly. He had pain on standing with the knee extended and on active flexion of the knee, pain about the knee with each step and pain in the lower posterior part of the left thigh when the left leg was crossed over the right knee. At operation, with local anesthesia, a mass the size of a hen's egg was found. This was visible, however, only when the knee was actively flexed. The muscle was also in a relaxed condition. Mattress sutures were used to shorten the muscle. An excellent result was obtained.

The mechanism of a muscle's tearing is of interest. McMaster,³ in experimental work with ruptured muscles and tendons, concluded that muscles are most frequently ruptured by indirect violence when they are in a contracted state. The muscle belly is torn across or the musculotendinous junction is separated. He found that when a normal muscle with tendon attached is subjected to a severe strain the muscle is injured as just stated or the insertion of the tendon is pulled away. Lexer⁴ has pointed out that occasionally a muscle may be ruptured while in a resting state by indirect violence. Direct trauma may produce a rupture, as shown by Montgomery,⁵ who had a case in which the triceps was torn transversely owing to a severe blow on that muscle.

The muscle tissue changes following rupture are generally agreed on by pathologists. Boyd⁶ stated that a torn or injured muscle is repaired by fibrous tissue and that no new muscle fibers are formed. Blood is poured into the gap and union results from formation of fibrous tissue. Karsner⁷ expressed the belief that regeneration of muscle tissue depends on the extent of the injury and the degree of involvement of the perimysium. If the destruction is extensive the muscle buds cannot bridge the gap and the area is filled with scar tissue. Smith and Gault⁸ stated that striated muscle, to all intents and

purposes, is incapable of actual regeneration. When injury involves muscle cells there is an abortive attempt on the part of the sarcolemma to proliferate.

CONCLUSIONS

1. Fibrous tissue formation is inevitable in the repair of severe muscle tears, treated either conservatively or surgically.
2. The resulting fibrous mass should be given consideration in its relationship to adjacent nerves and vessels.
3. Further efforts to repair the muscle in this particular case would have undoubtedly produced additional scar tissue, with a recurrence of the nerve pressure symptoms.
4. An excellent end result, functionally and cosmetically, has been obtained by complete excision of the semitendinosus muscle.

3701 Maple Avenue—15 East Fourth Street.

Special Clinical Article

PHYSIOLOGY OF THE BILIARY TRACT

CLINICAL LECTURE AT ST. LOUIS SESSION

A. C. IVY, PH.D., M.D.

CHICAGO

AND

LEON GOLDMAN, M.D.

SAN FRANCISCO

The most common complaints for which patients seek medical aid are those referable to the digestive system. The biliary tract ranks high among the abdominal organs which give rise to these complaints. According to a recent report, 24.5 per cent of women and 9 per cent of men over 39 years of age who complain of "dyspepsia" have gallbladder disease.¹ Necropsy records reveal an incidence of gallstones varying from 6 to 32 per cent in the occidant; they also reveal an incidence of visible gallbladder disease varying from 50 to 66 per cent.² Thus, the frequency of gallbladder disease is such as to emphasize the importance of a clear understanding of the normal and applied physiology of the organ and the ducts with which it connects.

Since on previous occasions the physiology of the gallbladder and the sphincter of Oddi have been rather completely reviewed,³ this paper will deal chiefly with some of the more recent advances of practical import. (Space permits the citation of only a few references in this synoptic review.)

THE GENERAL FUNCTIONS OF THE GALLBLADDER

The evidence indicates that the gallbladder has two general functions: It serves as a pressure regulatory mechanism and as a bile reservoir for digestive purposes.⁴

Pressure Regulation.—In man and dog the secretory pressure of the liver amounts to approximately 30 cm.

of bile pressure. The maximum expulsive power of the gallbladder amounts to from 20 to 30 cm. The usual resistance offered by the "sphincter of Oddi" in man and dog amounts to from 9 to 25 cm., but the sphincter at times may offer as much resistance as 75 cm. of bile pressure. This is an important fact, since all animals that have a sphincter have a gallbladder apparently to prevent back pressure from being exerted on the liver.

Bile Storage.—All animals possessing a liver which forms relatively small quantities of bile, such as man, the dog and the cat, have a gallbladder which, by considerable concentration, from five to ten times, can store the twelve to twenty-four hour output of bile.⁵ This concentrated bile, rich in bile salts, is ready to be discharged in response to cholecystokinin, which is produced when fats and acids make contact with the intestinal mucosa.

CHOLECYSTECTOMY AND THE GENERAL FUNCTIONS

When a gallbladder that concentrates bile is removed, a temporary paresis of the sphincter is said to occur. Later the sphincter is thought to recover and to cause the dilatation of the ducts that is usually found in man

The only established effect of the removal of a gallbladder that concentrates bile is that dilatation of the ducts usually occurs.

THE ACTIVITIES OF THE GALLBLADDER

The activities of the gallbladder are absorption, secretion and motility. These have been discussed adequately in previous papers.¹⁰ A few points deserve reiteration. The acutely inflamed gallbladder does not visualize, concentrate or evacuate. After the acute inflammation subsides, the gallbladder may apparently function normally, subnormally or not at all. A noninflamed gallbladder with a hyperplastic mucosa concentrates exceedingly well. An inflamed gallbladder is capable of absorbing bile salts, and, at times, serum protein and even blood may exude into the lumen. Some of the changes in the activities of the organ occurring in several common disorders are outlined in the accompanying table.¹¹

FACTORS CAUSING OR PREDISPOSING TO GALLBLADDER STASIS

Stasis in the gallbladder will predispose to infection and to the formation of gallstones, which in time may

Gallbladder Bile (Human)¹¹

	Absorption	Concentration	Secretion	Visualization	Emptying	Bile Acids
Normal	Water Chlorides Sodium bicarbonate Bile salts (?) (small amounts) Cholesterol (?) (small amounts)	Bile salts Cholesterol Bile pigment Calcium	Mucus (nucleo-protein)	Present	Normal	50% cholic acid 50% noncholic acids
Pregnancy	High cholesterol High chlorides Low bile salts Low calcium	Mucus	Present, distended	Delayed during 2d and 3d trimester	
Obstruction cystic duct	Eventually all constituents of bile absorbed	Calcium pigment high; cholesterol low calcium (when present)	± "White bile" (mucus) "Calcium milk bile"	Absent	Absent	
Damaged gallbladder wall (cholecystitis)	Bile salts; hypertrophic rugae cause good absorption, if not inflamed	High chloride Low bile salt Low calcium High protein	Increased	Present to faint, or absent	Normal, delayed, or absent	33% cholic acid in chronic cholecystitis; 10% cholic acid in acute cholecystitis

and dogs after surgical or pathologic cholecystectomy.⁶ Studies on man show that complete incompetence of the sphincter after cholecystectomy is not usual.⁷ However, a relative paresis may have occurred, since one cannot measure in man the resistance of the sphincter prior to cholecystectomy. Also the sphincter may have already undergone the sequence of paresis and recovery as a consequence of preexisting disease of the gallbladder. Although the actual cause of the dilatation to the ducts has not been established, the change shows that the gallbladder has a function. Further, bilirubinuria will develop sooner in an animal without a gallbladder than in one with a gallbladder when the common duct is obstructed.⁸ Direct evidence showing that intestinal digestion is disturbed after removal of a gallbladder that concentrates bile is wanting.⁹

cause symptoms. Continued stasis leads to hyperplasia of the mucosa and lymph nodes in the dog.¹² The following factors cause or predispose to gallbladder stasis: (a) hypertonicity of the sphincter of Oddi; (b) inflammation of the ampulla; (c) obstruction or stricture of the common duct; (d) duodenal inflammation;¹³ (e) reversed peristalsis or hypertonicity of the duodenum;¹⁴ (f) inadequacy of fats, proteins or fruit juices in the diet; (g) narrowing or inflammation of the cystic duct;¹⁵ (h) obstruction of the cystic duct; (i) hypo-

tonicity of the gallbladder; (j) inflammation, fibrosis or obstruction of the gallbladder; (k) pregnancy.¹⁶

REFLEX EFFECTS OF GALLBLADDER OR BILE DUCT DISTENTION

Pain, nausea and vomiting are well known reflex symptoms in biliary colic. Inspiratory distress is reported in 25.5 per cent of patients with chronic cholecystitis and in 31.8 per cent when associated with jaundice.¹⁷ Impaction of a stone in the cystic duct is said to be especially prone to cause respiratory distress. It is now known that a rather sudden elevation of pressure in the gallbladder or ducts will cause pain, nausea and vomiting in man and the dog. The right half of the diaphragm is relatively fixed and shows a limitation of motion. The pain is abolished by section of the splanchnic nerves and the nausea and vomiting by section of the vagi.¹⁸ To abolish completely the associated respiratory disturbance, section of both splanchnics and vagi is required. Anorexia may occur in disease of the biliary tract. It is known that mild distention of the biliary tract will inhibit hunger contractions and diminish the tone of the stomach, which probably accounts for the anorexia.¹⁹ Further, distention causes pylorospasm and contractions of the pyloric antrum if nausea or vomiting occurs.²⁰ The gastric flatulence of biliary tract disease is probably not due to fermentation or to the passage of gas from the blood into the stomach, although this idea has not been disproved, particularly in those patients who have anacidity. However, it has been found that appropriate distention of the gallbladder—a distention that causes loss of gastric tone but no evident nausea—may cause "aspiration" of air into the stomach owing to an apparent relaxation of the stomach and abdominal muscles.²⁰ (This phenomenon is not easy to demonstrate. One of us has seen this occur a number of times in lightly anesthetized dogs with the abdomen open while the stomach was visibly relaxing and becoming atonic.) Changes in heart rate, extrasystoles and arrhythmia may be induced by distention of the biliary tract in the dog, which may explain the improvement in cardiac rhythm reported to occur after cholecystectomy in some patients.²¹ An analysis of the theories of referred pain indicates that pseudo-angina or cardiac pain with distress in the biliary tract or vice versa means that disease is present in both the coronaries and the biliary tract. The effect of distention of the biliary tract on the small and large intestine, according to our knowledge, has not been studied.

SPHINCTER OF ODDI

In recent years considerable knowledge regarding the sphincter of Oddi in man has been contributed.⁹ Its only clearly demonstrated function is that it is necessary for the filling of the gallbladder. Schwegler and Boyden's²² embryologic and anatomic study has clearly

established its independent development and has shown that a definite group of circular fibers, called the sphincter choledochus, invests the ampulla and common duct distal and proximal to their junction. Using intact subjects or patients with an intubated cystic or common duct, important contributions to the physiology and pharmacology of the sphincter or the resistance to the flow of bile into the duodenum have been made. Biliary colic has been produced in the intact biliary tract by causing the gallbladder to contract in the presence of a spastic sphincter. Magnesium sulfate instilled into the duodenum relaxed the sphincter and relieved the colic.²³ With the common duct intubated, the following observations have been made: (a) After recovery from the operation, the average sphincteric resistance is 15 cm. of water (from 9 to 25 cm.) pressure. (b) In patients with inflammatory lesions, such as cholangitis secondary to stone, it is not uncommon for the sphincter to remain irritable for several weeks²⁴ and the resistance to fluctuate from 30 to 50 cm. or higher. (c) A carbohydrate meal has no significant effect on the sphincter, but a fatty meal decreases resistance.²⁵ (d) Morphine, pantopon (hydrochlorides of the alkaloids of opium, principally morphine), dilaudid and codeine increase resistance and amyl nitrite, glyceryl trinitrate, theophylline and magnesium

Fig. 1.—Effect of distention of the colon (A) before and (B) after section of the hepatic nerves on bile formation.

sulfate decrease resistance.⁷ (e) In the presence of a spastic sphincter, distention of the duct (from 15 to 20 cm. of water) causes the biliary colic type of pain.²⁶ Thus, the basis of the concept of biliary dyskinesia has been clearly and adequately demonstrated experimentally in man.

What causes a sphincter to become hypertonic, spastic or irritable is another question. Inflammation of the ampulla could do so by rendering the muscle hyperirritable; but, strictly speaking, this would not be a functional disturbance. Hypertrophy of the sphincteric muscle has been demonstrated,²⁷ but the cause of the hypertrophy is unknown. Reflex causes have been postulated but not proved. Inflammation or an irritable duodenum might involve the sphincter directly or indirectly.

Can the sphincter of Oddi be caused to contract reflexly? This is obviously an important question. The question has particularly intrigued us because com-

plaints of constipation and biliary tract disorders are so frequently associated and because constipation and biliary tract disease are prone to develop in pregnancy.

For example, with regard to pregnancy, it is reported clinically that from 70 to 90 per cent of women who have gallbladder disease necessitating operation are mothers.²⁸ Delayed evacuation in the latter part of pregnancy has been observed in man and animals.²⁹ Potter and others³¹ have found that the bile in the

Fig. 2.—Effect of stimulation of the inferior mesenteric plexus at 1 on the resistance to the flow of bile through the sphincter of Oddi into the duodenum. Note that stimulation of the plexus caused a temporary contraction of the duodenum and a more prolonged increase in the resistance to the flow into the duodenum.

gallbladder late in pregnancy is chemically altered. This is brought out in the accompanying table. The occurrence of constipation during pregnancy is well known. Blalock³⁰ has reported constipation as a symptom in 62 per cent of 735 patients in whom gallbladder disease was proved by operation. The incidence of cholecystopathy is doubled in persons with diverticulosis of the colon³¹ and in patients with peptic ulcer and recurring appendicitis.³² Many other clinical reports indicate the possible existence of a causal relationship between abnormal functioning in the alimentary tract, particularly the colon, and cholecystopathy. This possibility is emphasized by the observation of Boyden and Birch³³ that faradic stimulation of the peritoneal surface of the duodenum, jejunum and cecum in animals caused an enlargement or relaxation of the gallbladder.

The retarded evacuation of the gallbladder during pregnancy might be due to (a) very thick bile due to reflex inhibition of bile secretion, (b) reflex hypertonus of the sphincter and duodenum, (c) reflex inhibition of the gallbladder, (d) the action of sex hormones on the gallbladder or (e) a metabolic change in the chemistry of the bile. Constipation might predispose to cholecystopathy by the same mechanisms except that of the sex hormones. We have to date tested only two of these possibilities, namely, a and b.

EXPERIMENTAL

The Effect of Distention or Stimulation of the Colon on Bile Secretion.—Dogs were anesthetized and the bile duct was cannulated for the collection of bile; the cystic

duct was tied. The flow of bile was recorded electrically. The colon was distended with water or its nerves were stimulated electrically.

In twelve of fourteen dogs, distention of the colon with water reduced the secretion of bile by 50 per cent (fig. 1). Stimulation of the central end of the colonic, inferior mesenteric or superior mesenteric nerves of sixteen dogs caused a similar inhibition of bile secretion. Section of the hepatic nerves prevented the inhibition of secretion. This proves that the decrease in secretion was reflex in nature. When the bile flow was brisk after an injection of bile salts, the secretion was more difficult or impossible to inhibit. Distention of the proximal colon appears to be more effective than distention of the distal colon in eliciting the inhibition.

The Effect of Stimulation of the Colonic Nerves on the Sphincter of Oddi and the Duodenum.—The method of recording changes in the resistance of the sphincter and in the tone of the duodenum used previously in our laboratory was employed.³⁴ In brief, it consists in raising the pressure in the bile duct until a flow into the duodenum is established; then the colon is stimulated and the flow ceases. Then the pressure in the bile duct is raised until the flow appears. Simultaneous records of duodenal motility are made with a balloon.

In 90 per cent of the experiments, which were repeated several times in thirteen animals, stimulation of the nerves of the colon or inferior mesenteric plexus caused an increase in resistance of the choledochoduodenal mechanism (fig. 2). In 75 per cent the duodenal motility was increased and was associated with an increase in the resistance to the flow of saline solution into the duodenum. In most of the tests the increase in resistance outlasted the duration of the stimulation and in half of the tests the increase in resistance outlasted the increase in duodenal tone. The increase in resistance varied from 5 to 21 cm. of saline solution pressure (fig. 3).

Fig. 3.—Effect of stimulation of the colonic nerve on the resistance to the flow of bile into the duodenum. At 3, the nerve was stimulated. At 4, fifteen minutes later, the pressure in the common duct had to be elevated 12 cm. of pressure to obtain a return of flow. At 5, the nerve was stimulated again and the pressure had to be elevated 9 cm. more to reestablish a flow. At 6, the nerve was stimulated again. Thus, two stimulations of the colonic nerve increased the resistance from an original of 23 cm. to 54 cm., an increase of 21 cm.

COMMENT

The results of these experiments provide two mechanisms by which constipation may promote gallbladder or biliary tract stasis. Although they tend to confirm clinical impressions and observations, they cannot be directly applied to man. They are sufficiently decisive and important to indicate prophylactic therapy and to stimulate research to ascertain whether such mechanisms actually operate in man. There is no a priori reason to doubt their existence in man.

SUMMARY

Experimental results show that constipation or irritation of the colon or stimulation of the various divisions of the splanchnic nerves may predispose to stasis of the biliary tract by decreasing bile formation and by increasing the resistance to the flow of bile through the sphincter of Oddi into the duodenum.

303 East Chicago Avenue—University of California Hospital.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

MERIT SHORT WAVE DIATHERMY NOT ACCEPTABLE

Manufacturer: Merit Health Appliance Company, 1301-1303 South Lorena Street, Los Angeles.

An apparatus brought to the attention of the Council recently in behalf of public welfare is the Merit Short Wave Diathermy Unit. The Council concludes from an advertising folder called "Now! Short Wave Diathermy in Your Home . . . Relief Without Drugs" and from a letter addressed to a dealer that the unit is sold directly to the public for self treatment of disease. To quote, "ADVANTAGES OF HOME TREATMENT. . . . There when you need it—The old axiom 'an ounce of prevention,' etc., holds true today. Therein lies one of the chief advantages of having MERIT SHORT WAVE DIATHERMY in your home right when you need it. When the ailment is in its initial stages it is there ready to use and its application may prevent further progress of the disease. MERIT SHORT WAVE DIATHERMY can be used by every member of the family."

According to the advertisement, the device is portable and includes two pad electrodes as accessories, with sinus applicators available. According to the letter to a dealer, the apparatus utilizes two vacuum tubes of the T40 type. The manufacturer states that the maximum output for the unit is rated at 100 watts, and that the input for an average treatment is 225 watts. It operates on 110 volt 50 or 60 cycle alternating current.

Among the objectionable features that have been noted in the advertising is that the device is advocated for the effective treatment of many diseases for which the use of diathermy has not been substantiated, the treatment apparently to be self prescribed and administered by laymen. Among the ailments suggested for treatment are common colds, bronchial asthma and bronchitis, aching feet, sinus infection, "ailments common to women," high blood pressure, "agonizing pain" and "many stubborn diseases." It is stated that the unit is easy to use and that it "is so simple that even a child can operate it." Other objectionable statements in the advertising and letter include ". . . the old methods of application (of heat) are ineffective, uncertain and uncomfortable," "Short Wave Diathermy . . . countless thousands of sufferers have found it to be one of the safest, pleasantest, and most effective methods of treatment ever discovered." "It is similar to and as effective as the larger sets used by physicians, but is especially designed and simplified for home use." The firm suggests that diathermy be used for the destruction of bacteria, but no evidence is available that such an apparatus as this will cause bacterial destruction in the human body.

In the opinion of the Council, the Merit Health Appliance Company appears to be promoting an instrument in a way that is detrimental to public interest and to rational therapeutics. Sales methods which promote self treatment of disease by those unqualified to practice medicine and appeal to the public with unscientific persuasions may harmfully enhance a feeling of false security on the part of the public.

In view of the foregoing report, the Council on Physical Therapy voted not to accept the Merit Short Wave Diathermy Unit for inclusion in the Council's list of accepted devices.

BURDICK IONOPHORE ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The Burdick Ionophore generates galvanic current designed for use in iontophoresis, muscle stimulation and medical electrolysis (removal of hair). It is a portable unit with a front cover which is removable in order to expose the dials. Standard accessories include negative and positive patient cords, line cord, 2 foot cords with bulldog clips, one 6 by 8 inch Morse surface electrode and electrode material for iontophoresis. It weighs 26½ pounds and its dimensions are 10 by 11 by 14½ inches.

Burdick Ionophore.

The unit is equipped with two valve rectification and an extra capacity filter. The firm claims that it generates ample, smooth electric current, which, in order to prevent pain and electric shocks, is automatically built up slowly at the turning on of the power and gradually decreased to zero at the termination of the treatment. One voltage control is adjustable for "low, medium and high" and a milliamperage control is adjustable to the given ranges of voltage up to 60 milliamperes. A pilot light indicates when the desired intensity of current is reached and glows throughout the treatment; an automatic timer shuts off the current at the designated time. The resistance of

1. Oscillogram. Load 1,500 ohm resistance. Current 20 milliamperes.

2. Oscillogram. Load 1,500 ohm resistance. Current 40 milliamperes.

3. Oscillogram. Load 1,500 ohm resistance. Current 60 milliamperes.

4. Oscillogram. Load 3,000 ohm resistance. Current 20 milliamperes.

the patient's circuit, an index of the efficiency of the electric contacts, is measured by a resistance meter operating through an independent circuit. The polarity of the electrodes may be reversed by a control on the panel, eliminating the need of reversing the leads during a treatment. Models are available for operating on 110 volt 60 cycle alternating current or 110 volt direct current.

The Council investigated the electrical characteristics of the Ionophore by a string oscilloscope and obtained tracings of the current output on photographic films. The oscillograms were made with a stationary film since the output was continuous. The second element of the oscillograph was held at the center of the film to provide a guide line for comparison.

These oscillograms were made under the following conditions: Numbers 1, 2 and 3 were made with a load resistance of 1,500 ohms but the output currents were 20, 40 and 60 milliamperes respectively. Number 4 was made with a 3,000 ohm load and an output current of 20 milliamperes.

This direct current was filtered through a condenser to eliminate the direct current component and no ripple was apparent.

The resistance meter found on this machine is a standard type much used in making resistance measurements. As such, it performs within acceptable limits of accuracy. It has no effect on the other functions of the machine. In establishing the external circuit for this unit, many variables would be encountered, such as moisture in the skin and in the electrodes, area of the path, the current traveled and the chemical substances at the points of contact of the electrodes. With this meter such variables can be integrated into a single value in ohms.

The unit was submitted to a qualified physician for clinical trial and investigation, and he reported that it gave satisfactory service.

In view of the foregoing report the Council on Physical Therapy voted to accept the Burdick Ionophore for inclusion in the Council's list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.

PAUL NICHOLAS LEECH, Secretary.

ASSAY STANDARDS FOR CHORIONIC GONADOTROPIN

Accuracy in therapy with chorionic gonadotropin preparations has been seriously affected through the use of standards based on biologic reactions, the activity of such preparations being generally stated in terms of rat units. The rat units of the various firms marketing chorionic gonadotropin differ, however, to a varying extent. Some firms employ an assay method based on a minimal ovarian response in the immature rat, others use the induction of an estrous vaginal smear as the end point of their assay. According to impartial sources¹ there may be 100 per cent or more variation in assays by these two methods. Furthermore, there is a significant difference when even the same methods are used by different laboratories. Thus, administration of such material labeled in rat units leads to improper and unscientific dosage.

In an effort to avoid the confusion associated with bio-assays, the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations has devised and adopted an international standard of chorionic gonadotropin. This international standard is described in the memorandum of the League of Nations Health Organization which is appended to this report.

As the adoption of such a standard in this country would contribute to more reliable therapy, it appeared desirable that the Council consider for adoption a similar standard. In preparation for the Council's possible action the Advisory Committee on the Nomenclature of Endocrine Principles was consulted by questionnaire. The replies from the members of this committee were practically unanimous in recognizing the need for a suitable standard and in approving the international standard as adopted by the League of Nations Commission.

1. D'Amour, F. E., and D'Amour, M. C.: *Potency of Certain Commercial Hormone Preparations*, *Endocrinology* 22: 583 (May) 1933. Gaensbauer, Ferdinand, and Bradbury, J. T.: *Comparative Potency of Commercial Anterior Pituitary-like Preparations*, *ibid.* 24: 867 (June) 1939.

The Council therefore voted that the international standard for chorionic gonadotropin as devised by the League of Nations Health Organization be adopted by the Council and that firms whose preparations of this substance are considered for acceptance be required to assay the activity of their material according to this standard and label such activity in international units.

The international standard for the gonadotropic substance of human urine of pregnancy, chorionic gonadotropin, is appended.

LEAGUE OF NATIONS HEALTH ORGANIZATION MEMORANDUM

INTRODUCTION

During 1937 and 1938 an inquiry was made among interested workers as to the practicability and desirability of establishing an International Standard for the gonadotropic substance of human urine of pregnancy. It was recalled that preparations of this substance were standardized in a great variety of ways and that there was no method of equating the various types of units, defined in terms of animal reactions, used by different workers and manufacturing organizations. The survey showed that there was complete unanimity as to the desirability of establishing a standard, and the offers of material received from various quarters made it evident that there would be no practical difficulty in constituting a standard preparation in adequate quantity to serve world requirements.

At the third International Conference on the Standardization of Hormones, held in Geneva in August 1938 under the auspices of the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations, the results of the preliminary survey were considered and it was unanimously decided to arrange for the establishment of an International Standard for the gonadotropic substance of human urine of pregnancy.

The conference had before it the results of a cooperative examination of the various contributions offered toward the proposed standard, and they were able to formulate details of the manner in which the contributions should be mixed. They also defined a unit of activity in terms of the proposed mixture, subject to confirmation after specimens of the mixture had been assayed by members of the conference.

The contributions were subsequently mixed as arranged and a specimen approved by each member of the conference. The standard was established, and the unit brought into current use on April 1, 1939.

PREPARATION AND FORM OF ISSUE OF THE INTERNATIONAL STANDARD

Contributions from six sources were used in preparing the standard, substantial amounts of material approved by the conference having been generously provided by each of the following:

Boots Pure Drug Co., Ltd., Nottingham, England.
I. G. Farbenindustrie Aktiengesellschaft, Elberfeld, Germany.
Løvens Kemiske Fabrik, Copenhagen, Denmark.

Several of these preparations were already largely diluted with lactose and, as a first step in the mixing of the contributions, those preparations not already so treated were diluted to an activity equal to that of the most active diluted preparation by the addition of an appropriate amount of lactose.² At this stage a bulk of material amounting to about 800 Gm. was obtained. The material was then dried by exposure to P₂O₅ in vacuo and made into tablets of approximately 10 mg. without the addition of further excipient. A test weighing of tablets showed that 86 per cent were within ± 5 per cent of the 10 mg. aimed at.

The tablets were then packed in lots of twenty-five in small amber tubes, which were plugged with cotton wool and placed in ampules. The ampules were evacuated, filled with pure, dry nitrogen and sealed. A cork to fit the inside amber tube was

2. The whole of the contributions were then carefully mixed and further diluted with an equal amount of lactose.

also enclosed in each ampule. This method of double packing was devised to ensure the exclusion of oxygen from the finally sealed ampule, as laid down in the Report of the Conference, and at the same time to provide a suitable container for the tablets after the ampule had been opened and discarded. The finished ampules were transferred to the cold-room and are maintained constantly at a temperature of -2°C ; 2,854 of these ampules, each containing twenty-five 10 mg. tablets, were prepared. The standard is kept by the Department of Biological Standards, National Institute for Medical Research, London, N.W. 3.

The whole of the mixing, compressing and packing of the standard was generously carried out by Burroughs Wellcome & Company as a contribution toward the work.

DEFINITION OF THE UNIT

The definition of the unit adopted by the third International Conference is as follows:

The specific gonadotropic activity of 0.1 mg. (= 100 gamma) of the standard preparation shall be the international unit for recording the activities of all gonadotropic preparations of human urine of pregnancy, but only of such.

The unit so defined is an amount of activity very similar to that required, under the conditions used by many workers, to cause cornification of the vaginal epithelium of the immature rat.

SUGGESTIONS FOR USE

After the ampule has been opened, the inner tube should be removed, freed from cotton wool and closed with the cork provided. One or more tablets, each of which contains about 100 units, should be removed as required. The tablets are as constant in size as is practically possible, but it is essential that they should be weighed before use, so that a solution can be made of an exactly known strength, on the basis of 10 units for each milligram of ascertained weight. The tablets dissolve very readily in water or saline solution.

After the ampule has been opened, the amber tube containing the tablets of the standard preparations should be kept in a small desiccator containing P_2O_5 .

USE OF STANDARD IN BIOLOGIC ASSAY

The following recommendations for use of the standard are taken from the Report of the Conference, Bulletin of the Health Organisation of the League of Nations 7:889, 1938.

"The only tests for the comparative determination of gonadotropic activity, in units as above defined, on which the Conference has evidence to justify recommendation, depend on:

(a) The observation of a direct or indirect gonadotropic effect, shown by morphological changes in the gonads;

(b) The observation of secondary changes in the accessory reproductive organs, in animals not deprived of their gonads. When this type of test is used, the absence of substances directly causing such changes in the accessory reproductive organs should be assured by control tests on animals deprived of their gonads."

GLYCOLIXIR NOT ACCEPTABLE FOR N. N. R.

The number of inquiries which are received by the Council on Pharmacy and Chemistry concerning Glycolixir (E. R. Squibb & Sons) indicates the desirability of the publication of a report on the status of this preparation.

Glycolixir (Elixir Glycocolli Squibb) is the trade name for a preparation manufactured by E. R. Squibb & Sons, New York, which is stated to be a "tonic elixir" developed for use in patients "lacking considerably in energy," for whom a drastic regimen is unnecessary or unsuited. It is said to contain 28 grains of aminoacetic acid (glycocolli) per tablespoonful ($\frac{1}{2}$ fluidounce), indicated on the label as the average adult dosage. This represents approximately 1.8 Gm. of aminoacetic acid (glycocolli) in 15 cc. of the mixture. The vehicle is stated to consist of a "specially blended base of fine wine." The label also declares the presence of ethyl alcohol (12 per cent by volume).

The rationale of using such a preparation as a "tonic" on the basis of its aminoacetic acid content may be questioned. Several brands of aminoacetic acid N. N. R. stand accepted on the basis

of the reported effectiveness of these preparations in myasthenia gravis, progressive muscular dystrophy and pseudohypertrophic muscular dystrophy. There is no satisfactory evidence to warrant recommendations for use of the substance in combating fatigue such as might be encountered in patients for whom a "tonic" may be considered desirable. There is likewise no suitable evidence in support of the claims for the value of aminoacetic acid in stimulating appetite.

In a recent report (THE JOURNAL, July 8, 1939, p. 127) the Council on Foods has discussed available evidence in support of the claim that increased muscular endurance and delay in fatigue follow the ingestion by healthy men of gelatin, a protein which contains about 25 per cent of aminoacetic acid. In the opinion of the Council on Foods the available evidence does not justify the claims made.

In Squibb and Sons' advertising pamphlet "Glycolixir," on page five, there appears a quotation taken from the *Proceedings of Staff Meetings of the Mayo Clinic*, attributed to Dr. Russell M. Wilder:¹

"I am satisfied that I have been capable of more sustained effort since taking glycine, and other healthy subjects will tell the same story."

In a recent communication to the headquarters of the American Medical Association, Dr. Wilder has stated that the quotation was made without his permission. He further stated that the omission of the clause with which the original sentence ended completely changed its significance. The clause ending the sentence is quoted from his letter as follows: "but testimonial evidence such as this will not satisfy the critical mind." Dr. Wilder also indicated that the experiment on himself demonstrating a reduction of the output of creatine during exercise following the use of glycine was inadequate evidence of the effectiveness of this drug in muscle fatigue. He stated that it represented "an illustration of the kind of evidence which would need to be accumulated before conclusions could be drawn."

Despite the lack of suitable basis for its claims, the firm suggests the use of the product for the treatment of children who are underweight. Two dosage forms are available: The "Elixir," already described, and "Tablets," containing 1.0 Gm. of aminoacetic acid. The tablet form is claimed to be useful whenever the alcohol in the elixir is undesirable. The average dosage for both children and adults is stated on the bottle label of the "elixir." While this in itself is not objectionable, it is obvious that it suggests the usefulness of the elixir in children for the purpose of combating loss of weight, appetite or endurance. In the opinion of the Council this claim is unwarranted not only on the basis of insufficient clinical evidence but also because it may encourage the use of alcohol medication in children, or in adults suffering from muscular dystrophy. In either case the use of alcohol is contrary to the best modern therapeutic practice. If only the tablet form of Glycolixir was intended for such uses, no reference to dosage for children should appear on the label of the "elixir." It would seem, however, that the recommended adult dosage of two tablets three times daily could not be expected to be effective for such use as is recognized by the Council for aminoacetic acid, N. N. R., wherein from 20 to 30 Gm. is the recommended daily dosage. For this dosage the tablet form of Glycolixir would necessitate administration of from twenty to thirty tablets daily. It is apparent, therefore, that Glycolixir in both forms is intended for use as a "tonic," for which purpose the Council objected on the grounds of unwarranted therapeutic claims.

The Council declared "Glycolixir" unacceptable for inclusion in New and Nonofficial Remedies because (a) there is inadequate evidence to establish the claims made for the efficacy of its active ingredient, aminoacetic acid (glycocolli, glycine), in conditions other than various muscular dystrophies, (b) its alcoholic content is undesirable as a component of medication intended for children, (c) it is promoted in part by misquotation of references in advertising which is misleading, and (d) it is marketed under a proprietary name with unwarranted therapeutic claims in a manner which is inimical to the best interests of the public and the medical profession.

SATURDAY, DECEMBER 30, 1939

THE PLATFORM OF THE AMERICAN MEDICAL ASSOCIATION

The American Medical Association advocates:

1. The establishment of an agency of the federal government under which shall be coordinated and administered all medical and health functions of the federal government exclusive of those of the Army and Navy.

2. The allotment of such funds as the Congress may make available to any state in actual need, for the prevention of disease, the promotion of health and the care of the sick on proof of such need.

3. The principle that the care of the public health and the provision of medical service to the sick is primarily a local responsibility.

4. The development of a mechanism for meeting the needs of expansion of preventive medical services with local determination of needs and local control of administration.

5. The extension of medical care for the indigent and the medically indigent with local determination of needs and local control of administration.

6. In the extension of medical services to all the people, the utmost utilization of qualified medical and hospital facilities already established.

7. The continued development of the private practice of medicine, subject to such changes as may be necessary to maintain the quality of medical services and to increase their availability.

8. Expansion of public health and medical services consistent with the American system of democracy.

THE PRESIDENT GIVES INTERVIEW ON HEALTH PLANS

On December 22 President Franklin D. Roosevelt, in his regular interview with the press, gave definite intimation as to his point of view relative to proposed legislation in the field of health. According to a report from the United Press, he said that the administration is considering a program for federal construction of hospitals in areas where such facilities are lacking, and he intimated that the plan might be recommended to the coming Congress. According to the United Press, he said the program, if undertaken, would start modestly but could be enlarged as desired. No estimate of the cost has been completed, but the President emphasized, says the report, that it would cost less than the more extensive health and school programs proposed in bills introduced by Senators Robert F. Wagner, of New York, and Pat Harrison, of Mississippi.

According to the United Press, his comments indicated that he is dissatisfied with both these measures.

He said that the Wagner or Harrison bills would cost a lot of money and that the chief trouble was in the requirements for states to match federal funds. The new program he outlined would provide that the government bear 100 per cent of the hospital construction costs, retain title to the institutions and build them only in areas where local interests offered satisfactory assurances that they would operate and maintain the institutions.

Under a matched program, Mr. Roosevelt is said to have pointed out, those states which have the most money could obtain the most federal funds. "They already have the best hospitals and health conditions, he pointed out," says the United Press report, "while the poorer states have a lower health level and insufficient funds to obtain federal money on a matched basis. Since elimination of the PWA 55-45 matched money program, the President said, the federal government could afford to finance in a small way medical centers in those areas needing them. He suggested fifty hospitals as a start. He pointed out as an example one New York county of 100,000 population with six good hospitals and three Southern counties of the same population without any medical facilities. The cost of the program he has envisioned would not be great, but it would mark the first experimental steps to bring health facilities to those areas needing them most, he explained. The major part of the work would be done by the WPA as far as possible, he said. The Public Health Service and a committee of doctors would pass on the plans and determine the ability and willingness of localities to operate and maintain the institutions. The President said he had talked over the plan with a number of doctors and will discuss it soon with the American Medical Association.

"He said doctors from many locales had told him they were unable to raise capital to build hospitals but that if they could get small plants they could maintain and operate them. As outlined by the President, each institution would consist of a one story hospital building of two wings, one each for white and colored persons, and an administration building with clinic, operating room and laboratory. He estimated that each hospital would provide 100 beds at a cost of around \$150,000. The President emphasized that his program is no grandiose scheme for putting up hospital centers costing \$10,000,000 each and said he did not think the medical association's objections to government health programs would apply to such small hospitals. The President said that Miss Josephine Roche, former Assistant Secretary of the Treasury, was remaining with his Interdepartmental Committee on Health, but he said it did not mean that Security Administrator Paul V. McNutt was being eased out of the health program. He said a story to that effect about McNutt was crazy and made out of whole cloth."

Thus the President has recognized some of the objectives of the platform of the American Medical Association.

tion. He has recognized the primary objection inherent in the principle of grants-in-aid. The American Medical Association has approved the development of medical facilities where need can be shown, with provision for local administration and control. It has opposed the grandiose plans of the Wagner bill. The Board of Trustees and the officers of the American Medical Association have repeatedly offered their facilities and help and advice to the government in working out any sound plan for meeting immediately any needs which may be demonstrated.

EXPERIMENTING WITH STATE MEDICAL SOCIETY PLANS

While captious critics have been denouncing the American Medical Association as reactionary and obstructive, its members have been conducting numerous and extensive experiments during the last seven years in search of ways of organizing payments for medical service and adjusting the burden of medical costs to the abilities of varying economic classes. Never have so many, so varied or so significant projects been carried out in any other country. When the burden of medical care for the indigent disrupted the systems of county and township doctors, drained the resources of philanthropic organizations and became too heavy for gratuitous service by physicians to bear, the various state and county medical societies developed almost the only successful plans for efficiently distributing such resources as were available to provide medical care for the indigent.

During the period 1932 to 1938, between 200 and 300 county societies entered into contracts with relief authorities to provide medical service for the indigent. These were organized to include such protection to the interests of the patients and the public as free choice of physician and economical administration of the always insufficient funds. A number of county societies have also experimented with medical service bureaus for the low income classes. Some of these bureaus are still in operation and have been helpful to many persons in this class in enabling them to meet the costs of needed medical care. All these plans and all those which are now in operation are considered frankly as experiments to be expanded, restricted, altered or abolished as they prove their value in protecting the health of those served. If they are not found desirable they may be abandoned. The medical society stands the loss in time and money expended, but no political, financial or occupational vested interests are created and left behind to hamper further experiments.

Out of the extensive experience with county medical society plans sufficient knowledge has been gained to enable a number of state medical societies to undertake medical service plans on a statewide scale. At present at least fifteen states have such plans in various stages of development. These states include Arizona, Cali-

fornia, Connecticut, the District of Columbia, Massachusetts, Idaho, Michigan, Missouri, New Jersey, New York, Oregon, Pennsylvania, Utah, Vermont and Washington. In some states such arrangements have progressed little beyond endorsement by the house of delegates of the state medical society and the appointment of a committee to prepare a plan. In California, New York, the District of Columbia and Michigan such plans are already offering their service to the public or will do so within the immediate future. In Connecticut, Michigan, New York, Pennsylvania and Vermont, special enabling legislation has been obtained to insure the legality of such plans. In most of the other states, opinions have been obtained from insurance commissioners or other state authorities that the proposed plans are permissible under existing legislation.

There is a wide variation among these plans such as naturally accompanies the experimental stage in the establishment of any social institution. New York and Utah provide for payment of benefits in the form of cash indemnity rather than directly in service. Most of the others provide medical care under close supervision. There is some diversity in the income classes included, although most of them set the upper limit at around \$2,000 or \$2,500 for families, with a lower income limit for individuals. Missouri classifies premiums according to three classes of incomes and according to certain variations as to the number of dependents within each income class.

The information gained from these experiments and obtainable from statistical studies of morbidity and medical care is still insufficient to afford dependable actuarial figures covering the cost of medical care given on such prepayment plans. One reason for this uncertainty is the failure of most previous prepayment plans and especially systems of compulsory sickness insurance to place safeguards around the quality of the service such as to insure that medical standards shall be maintained as high as possible. Neither has any way yet been found to estimate the increased demand for medical care that always accompanies any plan of prepaid medical service.

In the proposed plans, prepayments vary from \$1.50 to \$2.50 a month for individuals, with a lower rate for additional dependents in the same family. Much of this variation is due to provisions which limit the service to what it is believed can be furnished at the rates charged. There are also provisions for deducting the cost of a certain proportion of the first services given in any one year from the coverage of the plan. These restrictions and the methods of acquiring members represent an effort on the part of medical societies to approach a more nearly actuarial basis for operation and to deal honestly with those who are to receive the service. California provides that the subscribers shall pay for the first two calls in any one illness, the District of Columbia for the first \$6, Michigan for the first \$5 and New York for the first \$10 expense in any one

given year. Some states also place a limit to the value of the service that is given in any single year. This is usually placed sufficiently high to cover all but the most exceptional illnesses and to make a substantial contribution where the total is not covered.

All these plans vest control in the medical profession, although several provide for lay members in their governing bodies. In all cases, arrangements are made to provide that medical standards shall be under professional control. The state medical societies have themselves provided, through appropriations from their treasuries and the gratuitous services of the organizing bodies, for the preliminary expenses of organization.

Current Comment

NEW VITAL STATISTICS HANDBOOK

The Bureau of the Census has completed a "Physicians' Handbook on Birth and Death Registration," developed to take the place of the older pocket edition. Copies of this book are being prepared for distribution in large numbers and will be shortly available on request from the Census Bureau and the state health offices. They can also be obtained by secretaries of county medical societies for distribution to their membership. As pointed out in the introduction, the information contained on birth and death certificates serves three cardinal functions: to provide citizens and official agencies with authentic records of births and deaths, to supply public health agencies and the medical profession with essential facts concerning births and deaths, and to furnish, for general social uses, statistical data such as life tables, population estimates and information on residence, migration and fertility. The book gives directions for filling and filing certificates of deaths and births. There is a brief description of the present registration system and the development of registration in the United States. The appendix contains the International List of Causes of Death with its index, a glossary of terms commonly used in vital statistics, a selected bibliography and selected tables and charts of vital statistics. Nearly all the information in this handbook will be needed at some time or another by virtually every practicing physician; distribution of the handbook is made easy and every physician would profit by availing himself of the opportunity to acquire a copy and becoming familiar with its contents.

PUBLIC INTEREST IN VENEREAL DISEASE

The number of clinics treating patients for syphilis during the last fiscal year was 2,405, an increase of 287 per cent over the number for the fiscal year 1930. The number of doses of the arsenical drugs used for the treatment of syphilis amounted in the last fiscal year to 10,656,253, an increase of 84 per cent over the number of doses of such drugs used in 1933. More than five and a half million blood tests for syphilis were made in the United States during the last fiscal year, whereas in 1930 only 1,632,083 blood tests were reported. The larger figures are no doubt the result

of greater public interest in venereal disease control, which has been stimulated by the development of more adequate facilities in the various states made possible by the Venereal Disease Control Act of 1938. Vonderlehr, in addressing a mass meeting in Pittsburgh, pointed out that continued progress in venereal disease control depends on constant improvement of standards in case finding, diagnosis and treatment. He recommended that every community in the United States which has a venereal disease control program check its program against nine elements considered by the U. S. Public Health Service essential to adequate control of syphilis. The nine points are: 1. A trained public health staff which knows how to deal with syphilis. 2. Regulations requiring reporting and follow-up on all cases of syphilis. 3. Facilities for treatment of all patients—both those who can and who cannot pay. 4. Free laboratory service available to all physicians and clinics. 5. Distribution of free antisyphilitic drugs to all physicians and clinics. 6. Blood tests for all pregnant women, and treatment where required. 7. Blood tests of all persons before marriage. 8. Blood tests in all complete physical examinations. 9. An educational program. Syphilis appears to be retreating, it was said, in those communities where the control program includes these fundamental points.

NEW LIGHT ON LEISHMANIASIS

Undaunted by war, the spirit of research is alive in China. Working independently, two groups of workers in Peiping have found that open cutaneous lesions in dogs contain Donovan bodies and evidently are an important factor in the spread of canine leishmaniasis. Feng, Chung and Hoeppli (a Swiss parasitologist)¹ from the Peiping Union Medical College and Ho² from the department of public health in Peiping share in the finding of these conditions in the Far East. Feng and Chung³ report that infection by sandflies from dog to dog was relatively easy and depended directly on the number of flagellates in the cutaneous lesions of the dog. The transmitting sandfly (*Phlebotomus sinensis*) is quite common in North China. It is still an open question whether the canine and human flagellates are identical, but much evidence points in this direction: dogs have been successfully infected with material from human leishmaniasis,⁴ canine cutaneous leishmaniasis and human visceral kala azar have been found in the same household,⁴ and the flagellates found in man, in the dog and in the sandfly were indistinguishable from *Leishmania donovani*.⁵ While cutaneous and visceral leishmaniasis in dogs in the Mediterranean basin has been described, canine leishmaniasis has been found rarely in India in endemic areas of human kala azar.⁶ The results reported from Peiping shed more light on this insidious infectious disease and are of particular importance for its control by the Chinese hygienists.

ORGANIZATION SECTION

ANNUAL CONFERENCE OF SECRETARIES OF CONSTITUENT STATE MEDICAL ASSOCIATIONS

Held in the American Medical Association Building, Chicago, Nov. 17-18, 1939

Address of Temporary Chairman

DR. ARTHUR W. BOOTH, Chairman of the Board of Trustees of the American Medical Association: I regard this conference of secretaries of extreme importance, perhaps next only in importance, to the House of Delegates. That body, of course, expresses the desires of the entire profession, but it is for you to disseminate that desire to the general practitioners throughout the states. It is customary to have a permanent chairman appointed from your body. I will entertain any nominations.

Dr. Crichton Barker, New Haven, Conn., was chosen and assumed the chair.

Address by Dr. Rock Sleyster

DR. ROCK SLEYSER, Wauwatosa, Wis. (after a description of the various functions of the Association): This wonderful building houses the major activities of your Association. It has been repeatedly enlarged in an effort to provide space to care for ever increasing demands on the Association for service. Each time it was thought the new space acquired would care for needs for many years to come, only to have its capacity taxed to the limit almost immediately. Each year demands grow, and at the present rate of increase in demands for service of present and proposed activities it will not be many years before another addition to the building will be necessary. May I urge that during your stay you visit and become as familiar as time will permit with the various departments of your headquarters and that you urge your membership as well, when in Chicago, to come here and learn first hand of the activities they sponsor, for it is your building, it is their building.

But do not forget, 535 North Dearborn Street is not the American Medical Association. You are the American Medical Association. The 115,000 members you represent, scattered far and wide over this great country, are the American Medical Association. This is only a building, housing your employees, functioning to carry out your directions. These activities have been developed only at your command. No officer, no board, no bureau, council or committee may formulate policy or institute major activities you have not authorized. We who have served here are your servants. We have tried to carry out your directions to the best of our ability. We have worked to develop the progress in medicine you, through your House of Delegates, have instructed us to perfect. We have at all times fought in defense of the policies and ideals you have adopted.

We as a profession have been accused of many shortcomings, but I am confident that there would be no cause for fear if the people could have the opportunity you have today to become familiar with the activities of the Association. And I venture to say that some of the thoughtless criticism by members of our own profession would be stilled by a visit here. I wish it were possible to require each state and county association to send representatives here each year. I know of nothing that would be productive of more good. You secretaries and editors can, however, do much to encourage visits and to carry to your members some better knowledge of the work being done here at their direction—some better realization of the resources available to them and the services which are and can be rendered to them.

I, for one, am proud of this great organization. I am proud of this great headquarters established and maintained without cost to its members. I am proud of the service it renders to its members, to science, to the public. Is this the story of selfishness, of greed? Or is it the realization of a great and unselfish ideal? Is it maintained for material benefits or is it the fulfillment of years of effort and purpose better to serve

humanity? Is this building a monument to personal interest or is it a temple dedicated to higher service, to the protection of the people against fraud and to the defense of the advancement of science and honesty in its application? Name one single activity here which does not bring a hundredfold more benefit to the people we serve than is brought to the individual member in material reward.

Members of the conference—if you will forgive the interjection of a personal motif in my conclusion—I want to say that I have participated in every conference of state secretaries and editors which has been held. I participated many years as a state secretary, as an editor, as a member of the Board of Trustees and this year as your President. It has been an occasion I have always looked forward to with keenest anticipation. To these conferences I am indebted for valuable information acquired and for inspiration to carry on in our great cause. If this were not reward enough for the effort and sacrifice to attend, I have been paid a thousand times by the friendships I have made. You are a truly outstanding group of men. In your hands, more than in any others, lies the destiny of American medicine, for your opportunity for service is greater than that given to most medical men.

It is with a feeling of sadness and regret that I realize this will be my last opportunity after all these years to participate in your proceedings in an official capacity. I want you to know, however, that as a private in the ranks I hope to be with you and "listen in" for old time's sake.

I, for one, cannot go along with those of a defeatist state of mind. I do not believe that the frontiers of medical service have been even reached. Granted that we maintain our ideals and objectives, that we remain true to our duty, that we remain steadfast in our defense of our age old standards of righteousness, I do not believe we shall be forced to defeat in our purpose to continue the advance in good medical care at a cost the people of this country can pay. We are 115,000 strong, a gain of 17,000 during the past five persecution years. We are a truly united profession. No selfish purpose has brought us together; we exist that we may better serve. Let us dedicate ourselves anew to the distribution of this type of service to even the poorest and the humblest home.

Medical Care in the United States

MR. C. ELLSWORTH NYBERG, Chicago: Any survey or statistical study should be preceded by a statement of the problem on which information is desired, an outline of the objectives to be attained, and the method to be used in the study. The Board of Trustees in their resolutions of December 1937 stated the purpose of the nationwide study of medical care. These resolutions were as follows: First, to determine for each county in the United States the prevailing need for medical and preventive medical service where such may be insufficient or unavailable; second, to develop for each county the preferable procedure for supplying these several needs. These resolutions were considered and approved by the House of Delegates of the American Medical Association at the annual session in June 1938. The Board of Trustees also established a Committee on the Supply of Medical Service, which cooperated with the Bureau of Medical Economics in the general conduct of this study.

METHOD OF COLLECTING DATA

The purpose of the study was to discover the number and nature of medical services and facilities in the counties studied, the agencies and methods that exist for the distribution of medical services, the degree to which the available services and facilities meet the medical needs of the various population groups in the surveyed counties and the extent to which desire

for medical services coincided with medical needs. State and county medical societies were asked to prepare reports, based on the factual data collected, containing recommendations of changes that were considered desirable in the methods of distributing medical care.

This term "medical care" as used in this study refers to the service and facilities available from physicians, dentists, nurses and pharmacists, hospitals and related institutions. Since the study was concerned primarily with the distribution of medical services, it was natural to seek information from those persons, agencies or organizations that in some manner arrange to provide medical service as well as from those persons who actually provide the services. Therefore, besides physicians, dentists, pharmacists, nurses and hospitals the sources of information included health departments, welfare and relief agencies, schools and colleges, industrial, fraternal and mutual benefit associations, group hospitalization associations, community health service organizations and other similar organizations.

Numerous statistical studies pertaining to health and medical care have been conducted in the United States since the beginning of this century. One favorite method used in such studies is the selection of a random sample of the population to be surveyed. In the American Medical Association study of the supply and demand of medical care a different procedure of collecting data was followed, since it was believed that a random sample would not be representative of the total population. Instead of applying a stereotyped formula to the problem, the method of obtaining the desired information was chosen to fit the nature of the problem.

Each county, and in some instances a local community within a county, has its own distinctive method of arranging and providing medical care to the indigent and low income groups. Health departments and relief agencies are organized and operated differently throughout the country. Therefore it was believed to be impossible to select a few counties to represent the methods of distributing medical care throughout the United States. The local means already established to provide and arrange for the distribution of medical care is an important factor in determining the method to be used in collecting the data pertaining to such distribution.

The second objective of the study was to recommend preferable procedures for meeting the needs indicated in the study. Before recommendations for changes in the method of distributing medical care could be made, it was necessary to determine the facts concerning the supply and demand for medical care in each county in relation to local conditions and available facilities.

FORMS USED IN THE STUDY

The forms used in this study for collecting data from various sources of information are familiar to you. Nine different forms and a summary sheet were prepared and distributed to the state medical associations for the use of county medical societies. The county medical societies in most cases appointed a committee to direct the survey and this committee was responsible for collecting and tabulating the data and preparing the summary sheet, one copy of which was sent to the state medical association and one copy to the Bureau of Medical Economics.

This study was not designed to produce figures that could be fabricated into a volume of statistical analyses which might be misused as absolute conclusions to describe the availability of medical care in any locality. The comments and suggestions on the method of distributing medical care and the degree to which available services and facilities were being utilized are more important than a mere knowledge of the number of physicians, hospitals and nurses in each county. Obtaining comments and suggestions on medical care was indicated in our statement of the objectives of the study. It seemed important to know not only where and in what way medical services are available but also what the best informed people thought was the preferable method of eliminating any barriers to the more complete distribution of medical care in a particular geographic area.

Frequently, in making a statistical survey, mathematical formulas and statistical devices are used in collecting and

tabulating the data simply because they are considered precise. A mere tabulation of the number of available medical facilities in a particular locality gives no indication of the extent to which such facilities are utilized unless it is also accompanied by information from persons or organizations who provide or arrange for medical services concerning their experiences with the existing methods of distributing these services and facilities.

EXTENT OF COVERAGE

The information collected on these nine different forms was studied, tabulated and summarized by the county committee in charge. The data and comments which were recorded on the original forms were then transferred to the county summary forms provided for that purpose. The greatest value and use of the information obtained in this study should be as a basis for future changes to improve the distribution of medical service.

A total of 862 counties in thirty-eight states with a total population of 49,278,000 were covered by this survey. If we consider persons living in towns of 2,500 population or more as urban, the population covered by this study can be classified as about two thirds urban and one third rural.

VALIDITY OF CONCLUSIONS

The conclusions arrived at from the study of these county summaries by the county committee in charge of the study were not generalizations but specific statements describing the actual experience of the persons responsible for distributing medical care and they were evaluated by a committee familiar with conditions in that particular area.

The amount of information and data contained in each summary sheet varies, just as the facilities and methods of providing medical care to the indigent and low income group varies in each county. The summary sheets contained sufficient data and information to enable the local individuals responsible for the distribution of medical care to discover leads or suggestions for improvements in the distribution of medical service.

Quite a number of committees in charge of these county studies prepared very thorough reports interpreting and evaluating the original data. These reports will serve as a basis for the county medical society to develop a program of improved medical care. These summary sheets and reports are, except for a few special studies, the only compilation of the facts concerning the supply and demand of medical care that have been made in these 862 counties.

STATE REPORTS

One copy of the county summary sheet was sent to the state medical association. This summary sheet then became the basis for a report on medical care for the entire state.

The state medical association's committee then added available material with regard to state institutions that participate in the provision of medical care. A few state medical associations prepared a report of their analysis and conclusions based on the compilation of county summaries and the additional data collected on state institutions. Among the states which made a very complete survey and prepared a state report were New Jersey, Maryland and Delaware.

DELAWARE

The Delaware report describes the available medical facilities and the conditions peculiar to that state and then lists the deficiencies brought out by this survey. In practically every instance these deficiencies were in relation to statewide institutions. Some specific needs indicated were more hospital beds for Negro tuberculous patients and for Negro maternity cases, more institutions for persons with mental diseases and chronic illness, and the care of the aged. Remedies already proposed or being developed to meet the indicated deficiencies were described.

MARYLAND

The Maryland report summarized the needs expressed by physicians, hospitals, welfare and relief organizations, health departments and schools. The physicians believed that there was a need for better classification of the indigent and more

adequate provision of public funds for their care. Hospital officials desired more thorough investigation of patients requesting free hospital service. Health departments and welfare and relief agencies stated that they worked in close cooperation with physicians and hospitals and that they experienced no difficulty in obtaining medical service for needy persons. The summary of the reports from schools showed that pupils examined and found to be in need of corrective medical treatment often failed to receive such treatment because of their parents' indifference or unwillingness to cooperate with school officials and physicians. All sources of information indicated a need for additional medical facilities for persons with chronic illnesses and mental diseases.

NEW JERSEY

One of the most complete and exhaustive state surveys was made by the New Jersey State Medical Society. Information was collected in every county and a summary form prepared including comments and suggestions for meeting existing deficiencies. The report by the state medical society discussed every phase of this study according to the source of information. The data obtained from each particular group were tabulated and analyzed. Conclusions based on these details were presented.

The various state departments which arrange for or provide medical care were considered separately. For example, one chapter described and discussed the facilities available in the state for the treatment of cancer; another discussed the venereal disease clinics. One of the more general conclusions arrived at in the New Jersey study was that hospital insurance was believed to be a great aid in meeting the problem of hospital expenses for the low income group. The New Jersey Medical Society then made further tests of the supply of medical care. In July 1938 the New Jersey Medical Society broadcast a statement by radio and in newspaper stories offering free medical care to any one in New Jersey needing medical care which he had been unable to obtain. In October, three months later, the president of the New Jersey Medical Society announced that only 127 requests had been received and turned over to the proper county medical society. Each request was investigated and medical services were provided where needed. According to the New Jersey Medical Society this investigation revealed that applicants could obtain medical care if they knew how to go about getting it. Many of the applicants had not attempted to obtain the services of a private physician nor had they presented their cases to health departments or relief agencies. Some had already received medical care but were not completely satisfied with it.

PENNSYLVANIA

The State Medical Society of Pennsylvania also made an excellent survey and prepared a well written report of the total area covered. This included fifty-one of the sixty-one counties in Pennsylvania. The report is organized as individual reports from each county. The state medical society committee prepared a short summary of the data and information on a statewide basis but it stated that the statewide report would be of less practical value than county reports. Each county report contained a description of the county, its population, a list of all the persons and organizations who arranged for or provided medical care, and a compilation of the amount of free medical services provided by each group during 1937. Following this there is a discussion of the need for expanding or enlarging certain medical facilities, and of why certain persons had not obtained needed medical care. This report of exact detailed conditions by counties is especially useful for further study of the demand and supply of medical care in each county. One county may have an excellent system of providing medical care to the indigent but such a system may not apply or may not be needed in other counties. Therefore a state report by counties may be of more practical value than a general report of the entire state.

KENTUCKY

The Committee on Medical Economics of the Kentucky State Medical Association prepared a complete report of factual data in relation to medical care in Kentucky. This report, which

was published in the August 1939 Bulletin of the Department of Health, contains a description and discussion of the population with regard to growth and economic status, a tabulation of all the medical facilities and organizations which arrange or provide medical services, and vital statistics for the entire state. This report contains a treatment of the same data for each county in Kentucky.

CHICAGO

Certain individual county medical societies in almost all the states conducted thorough surveys and summarized data into a concise and informative report. The Chicago Medical Society deserves special mention for the survey made of the medical care and facilities in Cook County. Every source of information was considered and called on to supply data for this report. Physicians returned 1,603 forms, dentists 370, general and special hospitals eighty-one, nursing organizations eleven, health departments eighteen, a district state health officer one, public and private relief agencies and social workers 285, public and parochial schools fifty-eight, colleges and universities seventeen, industrial organizations and union and benefit associations 258, and pharmacies 242. The complete report describing and discussing data obtained from these many sources makes a book of 268 pages, so organized that information on any particular group or institution can be easily found. Conclusions and interpretations of the Committee on Medical Economics of the Chicago Medical Society, which conducted the survey and prepared the report, are also included. A considerable portion of the report is taken up with individual comments and suggestions that support these conclusions.

OTHER COUNTY SUMMARIES

Some of the other county medical societies which made complete investigations and reports on the supply and need of medical care in their particular area were the Middlesex South District Medical Society in Massachusetts, the Monroe County Medical Society in Tennessee, the Providence Medical Association in Rhode Island, the Washington County Medical Society in Iowa, the Rock County Medical Society in Wisconsin, the Harris County Medical Society in Texas, the Vanderburgh County Medical Society in Indiana and the Marion County Medical Society in Kansas. These county medical societies tabulated the data from every known source and then prepared a concise report stating their conclusions and supporting them with comments as well as stating why they believed their conclusions were valid.

Any one interested in learning how a small medical society whose members are all engaged in rural medical practice made a thorough study of all the factors implicit to the distribution of medical care in a rural area and prepared a concise but still complete report of their conclusions should read the Monroe County Medical Society of Tennessee report. This county medical society of fifteen members had no special facilities or funds to carry out this study, but they experienced no undue difficulty in obtaining complete information from all sources as a basis for their conclusions.

The 614 other county medical societies which have not been mentioned returned summary sheets of the data they collected, including comments and in some cases special reports. All these summary sheets or reports contained specific information concerning medical care in that county.

VALUE OF COUNTY REPORTS

In interpreting data collected in a small area covered by a county there is little need for generalization, since each comment or suggestion can be treated individually. Special local features of distributing and providing medical care can be given the proper place and described in detail. Any claims or statements that medical care is not available can be investigated and a specific remedy suggested and applied.

The general summary based on all the county and state reports prepared by the Bureau of Medical Economics contains tables showing that 623 local medical societies in thirty-eight states conducted the survey in 862 counties which had a total population of 49,278,000. A total of 22,397 physicians and dentists and 16,290 other persons or organizations returned completed forms which were used in the study.

FREE SERVICE FROM PHYSICIANS

The returns from physicians and dentists were not always separated on the county summary sheets. The ratio of returns on the forms which did indicate physicians and dentists made it possible to estimate that about 17,000 physicians reported. These 17,000 physicians stated that they had served 2,927,108 persons without charge during 1937, that is approximately 6 per cent of the population covered by the study, but the total number of physicians reporting was approximately 27 per cent of the physicians practicing in the area. Therefore it can be safely estimated that between 10 and 15 per cent of the population received free service from physicians in the home and office during 1937. These same 17,000 physicians reported that they had donated 2,051,954 hours of free care to patients in the hospital outpatient departments and clinics during the year.

FORMS 1 F

An additional tabulation of the amount of free service rendered by physicians was made from data collected in the forms 1 F. These were actual weekly records kept by the physicians in three different weekly periods during the year and were returned directly to the Bureau of Medical Economics for editing and machine tabulation. According to the figures recorded on 9,936 weekly records, 835,716 patients received medical service in the home or office during one week. This represents an average of eighty-four patients who received some medical service from each physician during a week. A total of 9,840 weekly records of free medical services showed that 134,200 patients received medical services from physicians in the home or office for which no charge was made. This represents an average of about fourteen patients a week for each physician. According to these figures, about 16 per cent of the total number of patients seen in patients' homes or physicians' offices received free service. This percentage does not include patients served free in hospital outpatient departments or clinics or the number of patients who received service and later failed to pay. Previous studies indicate that about 20 per cent of the fees charged were not paid.

This compilation of free services from weekly records of physicians was made entirely separate from the general survey. The results obtained support the conclusions based on the general survey that from 10 to 15 per cent of the population received free medical services from physicians.

HOSPITALS—FREE SERVICE

A tabulation of the number of public charges and the number of free patients cared for in reporting hospitals also was made. Returns from 1,336 hospitals showed that they had cared for 505,128 public charges and 721,216 free patients during 1937. The type of hospital was not indicated in every case, so it was impossible to determine the total number of general hospitals and special hospitals or type of control—governmental, private or nonprofit. Such a breakdown can be made in each county, since the type of hospitals can be easily checked.

The total figures from hospitals can be useful as an indication of the amount of free hospital service, but one is limited in making any general statements concerning free care in hospitals for the total area since the size of the hospitals, the type and the ownership are not available in every instance.

METHOD OF OBTAINING INFORMATION ON LACK OF MEDICAL CARE

Each of the nine different forms used in collecting the data for this study contained a question as to any specific inability to obtain medical care. Each person filling out the form was requested also to supply comments or suggestions concerning any observed lack of medical care and to indicate the method which he believed should be considered in seeking a remedy for such a situation. The answers to these questions are of great significance, since they were directed not only to physicians but to the public health and visiting nurses, health department officers, welfare and relief officers and school officials. The activities of such individuals in each locality should make them aware of any deficiency in the medical facilities or in the distribution of medical care, since they have every oppor-

tunity to discover if any person is unable to obtain medical care. Since they are largely responsible for providing or arranging for medical care, they would be aware of any difficulty in furnishing medical care under existing systems of distribution.

Our conclusions on the deficiencies of medical care are based on repetition and consistency of replies from this group. The most significant feature of these replies is their general agreement in describing any local conditions that indicated a lack of adequate medical care or of special arrangements for providing it.

CONCLUSIONS ON LACK OF MEDICAL CARE

According to the expressed opinions of those best qualified to judge, there is no large group of individuals in any part of the surveyed area who were unable to obtain medical services which they desired. The few isolated cases in which individuals had not received needed medical services were usually found to be due to the fact that they either did not want medical service, made no attempt to obtain it or refused to accept free service.

It was evident also from the replies that institutions for the care of persons with mental diseases, chronic illnesses and tuberculosis needed to be increased or expanded. In most cases local programs were being developed to increase the facilities according to the needs and different conditions in each particular area.

Another general conclusion borne out by practically all the replies is that a large number of school children do not receive the medical care recommended after school examinations, owing to their parents' indifference or procrastination. These recommendations for medical services for school children were almost entirely for dental care, removal of tonsils and adenoids, and the provision of eye glasses.

The comments also indicated that most states and counties had not developed a successful plan for handling indigent transients. Such individuals were depending on free services from physicians, dentists and hospitals but in some areas the large number of transients made it necessary that the responsibility for their medical care be assumed by the local government.

These general conclusions based on consistent repetition of comments are useful in that they show clearly the need for developing certain general plans for improving the distribution of medical care.

A careful analysis of the material collected in this survey indicates that the important factor in improving the distribution of medical services is to develop and experiment with a specific program in a small area such as a county or city. There is no way in which a general plan can be prescribed for the whole surveyed area when there are such diversified existing conditions in each county and city. A plan usually works very well in one area because it has been developed to fit the needs and conditions in that area and therefore may not be applicable or beneficial to another area.

A practical solution for the indicated deficiencies in a given community must be developed according to the existing facilities and special conditions indicated in the county survey. Similar surveys to determine progress toward meeting the problems that were revealed in this present study can be made. These later studies will bring out new needs and will furnish suggestions for ways to meet them.

DISCUSSION

CHAIRMAN BARKER: Perhaps you will let me have a moment here to tell you briefly of the pattern we followed in my own small state of Connecticut. We had an idea that, if we could get the state government interested in such a study, provided it could be made under the proper auspices, the results would become a public document rather than a report of what might be accused of being a biased group, the medical profession. We went before the general assembly in 1939 with a rather extraordinary bill which, in the hurly-burly of other things, was passed. A commission is now at work, financed with state funds from the governor's executive budget. It has no definite appropriation. We are at liberty to retain the full time field workers and experts, and we are charged with reporting our observations and recommendations to the general assembly of 1941. That study is now under way. I

am the chairman of the commission making the study. In addition, there is another member of our state society, the superintendent of our largest hospital, a nationally known figure in the field of public health, who is connected with the Yale School of Public Health, another physician who is not a member of the state medical society, a retired public health official and a layman, a member of the minority party in our senate. Our document will be a public document and we shall be given the opportunity at least to recommend to our statesmen the deficiencies that exist in our state.

The Wagner Health Bill

DR. W. C. WOODWARD, Chicago: In the early part of the year the President sent to the House of Representatives a message: "Message of the President of the United States transmitting the annual message on Health Security." The President began: "In my annual message to the Congress, I referred to the problems of health security. I take occasion now to bring this subject especially to your attention in transmitting the report and recommendations on national health prepared by the Interdepartmental Committee to Coordinate Health and Welfare Activities.

"In August 1935, after the passage of the National Security Act, I appointed the Interdepartmental Committee to Develop Health and Welfare Activities. They have reviewed unmet health needs and the desirability of developing a national health program. They shall develop the outlines for such a program."

Then there is the reference to the notorious health conference held in Washington for the purpose of endorsing this particular program. We have these significant words from the President: "The objective of a national health program is to make available in all parts of our country and for all groups of our people the scientific knowledge and skill at our command to prevent and care for sickness and disability, to safeguard mothers, infants and children, and to offset through social insurance loss of earnings among workers who are temporarily or permanently disabled."

There is no distinction there between the attention that shall be given to persons who are able to provide medical services for themselves and those who are not, but "the objective of a national health program is to make available in all parts of our country and for all groups of our people the scientific knowledge and skill at our command to prevent and care for sickness and disability."

The President commended the report of the Interdepartmental Committee.

Those of you who are familiar with the Constitution know that all bills for raising revenue must originate in the House of Representatives. The Social Security Act is an act that proposes to raise revenue, so this message was addressed primarily to the House of Representatives. It was referred to the House Ways and Means Committee. The Committee on Ways and Means had decided that in proposing amendments to the Social Security Act it would limit its amendments solely to those having to do with what we may term economic relief rather than health relief.

Activities then were transferred to the Senate side on the initiative of Senator Wagner. We understood that the senator was engaged in the drafting of a health bill of some kind. We wrote to him, and I appeared at his office on various occasions trying to get in touch with him. I even had a letter of introduction from the Medical Society of the State of New York, but that did not secure contact. In fact, I have never been able to make contact with Senator Wagner regarding this bill. The bill, we learned, was being drafted by his legislative clerk, aided, I know, by various representatives of the Public Health Service, the Children's Bureau, the Social Security Board and outside agencies. I had no knowledge of the bill until the day it was introduced in the Senate. Then we had a carbon copy of it twenty-four hours or more in advance of the general public, but no chance to suggest amendments. That bill is supposed to implement this report of the Interdepartmental Committee. [Dr. Woodward then outlined the Wagner bill, S. 1620.]

Then came the hearings before the Senate subcommittee, which has issued a preliminary report. You may recall that the House

of Delegates of the American Medical Association proposed that grants-in-aid for health and medical services be given to any state on proof of need and that some proper agency be established to determine whether need had or had not been proved. The committee, however, unfortunately has stated the case very differently in its preliminary report. The committee said: "Some witnesses have objected to the grants-in-need pattern embodied in the bill. They have urged that there should be a federal officer with authority to approve aid to some states in dire need of assistance and withhold it from other states with lesser need. However, the questioning by the committee brought out that, the more closely these witnesses inspected the procedure necessary for an equitable grant-in-aid program, the closer they approached to just such a pattern as is embodied in the bill, with some divergence of opinion as to the amount of money to be authorized or as to the details of the standards to be followed in making allotments."

I sat through all the hearings. I heard, I think, practically every word that was said, and I challenge any one to show anywhere in the record any proposal that there should be a federal officer to pass on the needs of the states. But the American Medical Association recommended a federal agency which might be similar to the Reconstruction Finance Corporation; that might, for that matter, be the Reconstruction Finance Corporation itself, because the proposition is altogether the determination of financial need. Then there was certainly no reference to provide that there should be that distinction between those in need and those in lesser need. It was a question of need, proved to the satisfaction in the first place of the officer who is familiar with the program proposed and, second, to the proper financial agency.

In the course of the hearings, questions were repeatedly asked, often by Senator Wagner, sometimes by others: "Can you point out anything in this bill that will permit the state agencies to whom grants are to be given to provide medical services for persons of ample means to provide them for themselves?" Not one of the witnesses who appeared could point out anything in the bill that would permit a state health officer, or any other state officer, to provide hospital and medical services for rich people. But, as a matter of fact, there is absolutely not one word in the bill that limits the benefits to be conferred to persons who are poor, or even to persons in moderate means. The benefits that this bill proposes to offer are available to every one, from the richest millionaire in the community to the poorest citizen.

Here is a rather interesting point of view that the subcommittee has taken: "The appropriation sections of titles V, VI, XII and XIII of the bill include, as being especially among the purposes of the authorization, to assist rural areas, or, in title XIII, individuals suffering from severe economic distress. Some witnesses would go further in this direction. They recommend that the bill be amended so as to limit exclusively to needy or to medically needy persons the health services, financially aided by grants-in-aid contemplated by the bill. It is not always made clear, however, precisely how one or the other of these groups is to be defined without limiting the effectiveness of the health programs in the states so as to defeat the purpose of the bill for the improvement of the health of the population. We have already reviewed the overwhelming body of evidence submitted at our hearings showing that medical costs may be burdensome and medical care inadequate to tens of millions of our people in income brackets above the level of those who are in receipt of any form of public assistance.

"Any useful definition of the medically needy must recognize that a large proportion of the entire population may be greatly burdened by sickness costs and may at any time be among the medically needy, even though otherwise self supporting. Furthermore, many health problems transcend geographic, economic or social boundaries, for some health service must obviously be made available on a community-wide basis to all families and be paid for from general tax funds."

Then they proceed: "Other witnesses, representing large groups of population, have emphasized the inadequate services received by self-supporting families and individuals of small incomes. They have recommended that the bill be amended to require as a condition for the receipt of federal aid specific health insurance programs in the states to meet the needs of self-

supporting persons with incomes up to \$3,000, or even a higher limit." Then they point out the objection that may be raised by those persons to have anybody inquire into their ability to pay.

Those are the views that the subcommittee itself has set forth, and I think we shall have to be prepared to meet them. Some persons whose legislatures meet annually or who have a session only every other year have gotten the impression that in Congress a bill expires at the end of the session. That is not the case. It expires at the termination of the Congress. So this is still before the committee.

The bill has been demonstrated to be an entirely unsatisfactory and irrational and unreasonable bill. We are assured that the subcommittee will present a new bill sometime during the coming session of Congress. We have solicited the opportunity of participating in the framing of any such new bill. Up to the present, however, no opportunity has been afforded to join in the drafting of the proposed new bill or new amendments.

The burden of seeing that the bill that is to be enacted during the coming session of Congress, if any bill is enacted, is a sound bill is, more than ever, going to fall on those who represent state medical societies. You who are back home, who can make contacts directly and indirectly with your own congressional delegations, ought to make such contacts before they return to Washington in January. You ought to represent to them the readiness of the American Medical Association to go along in any rational program, and its eagerness to do anything it can to make any program that may be proposed a rational program—which the Wagner Health Bill is not!

The Platform of the American Medical Association

DR. MORRIS FISHBEIN, Chicago: The Board of Trustees has asked me at this point to interpolate a statement relative to a proposed platform for the Association.

The Board of Trustees recognizes that the policies adopted by the House of Delegates prevail. Therefore the platform which it sets forth is derived from sessions of the House of Delegates.

Following the report of the reference committee of the House of Delegates, twenty-two points in relationship to the Wagner bill were adopted by the House of Delegates. These represented the basis of the appearance of your representatives before the hearings of the subcommittee in Washington. In the report of those twenty-two points far more attention was given by the press of the country generally and, indeed, by physicians as well, to the opposition to the Wagner bill than was given to the five or six points which concluded and which were wholly constructive. These recognized that the American Medical Association, representing some 115,000 physicians, has a definite obligation to the people of this country in relation to the provision of medical service.

We have gained great objectives during the period which Dr. Sleyster so aptly characterized as the five persecution years. The medical profession of this country is capable of defending its faith in the principle of the private practice of medicine as the main principle in the development of medical practice in this country. We are not opposing now; we are asking the government to go forward with the medical profession in attaining a wider distribution of medical and preventive medical services based on actually demonstrated needs in various communities of the country. [Dr. Fishbein then presented the platform of the American Medical Association and the discussion as printed editorially in *THE JOURNAL* November 25, p. 1966.]

In a recent trip which I took through the Western states I learned of certain bills brought up in Western legislatures asking them to match federal appropriations. Federal officials came out to solicit those state legislatures to pass those bills with the wording developed in Washington, in order that Washington might then give to the state the money Washington had. In other words, the Congress appropriates the money, then federal agencies go out and sell to the states the idea of spending the money. The states may not ask for the money in the first place and may not want the money; sometimes it would be a considerable burden on those states to spend the money efficiently. That situation must be avoided in relation to any health legislation developed in this country.

Local determination is fundamental to the right of the individual states and communities to determine for themselves what their needs are and not to have their needs sold to them by the federal government. It is basic in maintaining the kind of medical practice, the kind of preventive medical practice that has prevailed in this country for so many years and which has given us the extraordinarily satisfactory conditions we have today. In the same message the President sent to the Congress, to which Dr. Woodward has already referred, the President pointed out that we have attained the lowest sickness and death rates in our history. Just yesterday the United States Public Health Service made the statement that our maternal mortality rate has dropped within recent years 23 per cent below former levels. This represents a tremendous gain in the control of maternal mortality. In other words, this country is not in the throes of a serious emergency, with people dying right and left for lack of medical care, with innumerable mothers' lives being wasted for lack of medical care.

There has been a vast propaganda in an endeavor to sell the national health program, so called, to the people. Now perhaps the federal agencies that have done so much to sell the program have begun to see the futility of their method of approach. Now they have gone back to the point where they sell themselves to the people instead.

HOSPITAL FACILITIES

If you were at the hearings in Washington, you got the idea that there has been no building of new hospitals in recent years in the United States. With PWA funds and WPA labor, and under the Federal Works Administration and innumerable other administrations, they have been building hospitals to a considerable extent. Recently Morrill, in analyzing hospitals built with federal funds in Michigan, showed that eight hospitals so built were unnecessary, showed that not one of the hospitals could function especially efficiently as a hospital, having no specialists, no laboratory, no x-rays and in many instances being close to large cities with magnificent hospital facilities. He showed in addition that not one of the communities in which the hospitals were put down could maintain those hospitals without something like \$5 to \$8 per capita annually as a tax on the local community for the maintenance of the hospital, something far beyond the ability of any small community in the state of Michigan to bear. Those are examples of the fact that there has been vast spending, uncontrolled, unscientific, uneconomic and unwarranted.

What we need is, first of all, utilization of space now existing in our nonprofit, voluntary hospitals—perhaps the best in the world—space which is up to now from 25 to 30 per cent not utilized. The propaganda in relationship to the building of hospitals with federal money is probably the worst of all the propaganda associated with the national health program. Obviously, what we stand for there is the kind of experimental programs that are already being attempted in many places and in many states, led by the medical profession itself, in an endeavor to gain under the American system of practice a wider distribution of medical service to all the people. Such experiments, properly controlled by physicians in the community according to the standards set by the American Medical Association for the quality of service, we can encourage to the utmost.

The introduction into this nation of a federal security plan whereby the nation itself, as a federal agency, will step intimately into the sickness and life of every person in the country will be the first step in the breakdown of American democracy. Indeed, all forms of security, compulsory security, even against old age and unemployment, represent a beginning invasion by the state into the personal life of the individual, represent a taking away of individual responsibility, a weakening of national caliber, a definite step toward either communism or totalitarianism. The people of this country today have begun to awaken to the insidious approach of such new forms of government.

Present Horizons

DR. AUSTIN A. HAYDEN, Chicago: The matters that have been presented this morning show clearly the differences of opinion in regard to the national health survey and to the survey that has been conducted by the American Medical Association. I must pay tribute as a private practitioner of medicine to the

efforts that Dr. Braasch and his committee have put forth in making that survey. I think it is one of the most helpful things the Association has ever undertaken. It is not completed by any means.

The need and the demand are the points by which principally these various reports differ. The need will never be completely met. All of the health surveys that have been made, of course, show greater need than is demanded. Few, if any, demands for medical aid have been turned down by physicians in physicians' offices, in physicians' clinics or in any place in which they work.

The Board of Trustees has recently held a meeting with the hospital groups, the American Hospital, the Catholic Hospital and the Protestant Hospital associations. A similar meeting has been held with the American Dental Association and with the American College of Physicians. Just yesterday a meeting was held with the American College of Surgeons, a most harmonious meeting. Think of the change that has occurred in the attitudes of various organizations in the past ten years. In that meeting every one desired that duplication be avoided by the two organizations, that every help should be given one to the other so that hospitals will not be examined too frequently to say whether or not they are proper places for sick people to be.

The platform is a positive program, designed to be applicable to every section of the country.

DISCUSSION

MR. C. S. NELSON, Ohio: I should like to direct a question to Dr. Woodward. What will be the attitude of the American Medical Association with respect to specific amendments to whatever bill is presented to Congress, whether it is the Wagner bill, a revised Wagner bill or some new bill? Before the last session every member of Congress in Ohio was interviewed by a committee of physicians. We paid particular attention, of course, to Senators Taft and Donahy. We had a definite understanding with most of them and, I think, if the Wagner bill had come to a real issue on the floor, we would have had an almost unanimous vote against it from the Ohio delegation. We have found in Ohio—and we are no different from other states, although I think we have a reasonable degree of success in legislative activities—that amendments are pretty valuable. Sometimes you can cure a bill pretty quickly with amendments. I think that is up to some body of the American Medical Association.

DR. OLIN WEST, Chicago: Perhaps some things need to be said that have not yet been said with respect to the status of this legislation. For the first time in several years the American Medical Association has been given assurances from official sources, including a member of the subcommittee of the Committee on Education and Labor which conducted the hearings on the Wagner bill, that the representatives of the organized medical profession will be given opportunity to confer with that committee and perhaps with others who may be interested in the objectives of legislation designed to extend public health and medical service. I have within the last few days received a very encouraging letter from Senator Murray. Apparently there have been no meetings of the subcommittee of the Committee on Education and Labor of the Senate since the hearings on the Wagner bill were closed. Senator Murray specifically states that there will be no further meetings of the committee until some time in January. There are those who are constantly urging the American Medical Association to introduce a bill of its own. There are those who did insist for a considerable time that we should amend the Wagner bill in its various sections. It is my personal opinion that that would have been highly inadvisable. For the last ten years or more ardent proponents of compulsory sickness insurance have utilized their utmost endeavors to force the American Medical Association into the position of having introduced legislation in the Congress of the United States to provide for a great, comprehensive system of voluntary sickness insurance that would be, after all, politically controlled. It would be the first and the inevitable first step toward the enactment of other legislation providing for compulsory sickness insurance. I think we have been crippled by the assumption of a defeatist attitude on the part of many of our own members. I don't believe there is any occasion for the assumption of any defeatist attitude. The principles for which organized medicine

stands are strong enough and meritorious enough, humane enough and sound enough to deserve the support of every physician and of every intelligent citizen.

DR. EDWARD H. CARY, Dallas, Texas: The gentleman from Ohio raised a question which I think was embarrassing to all of us in Washington. Whenever a bill comes up in Washington, written by any one and presented, if you go there to a hearing the man who is interested in that bill is going to run you up a tree to find out "How would you amend this bill to make it satisfactory?" If you are not prepared to amend the bill, he will say "Well, you are just against all legislation." In defense of the position of our committee that went to Washington, I would say that I called on several senators, and one commended us for not being drawn into the position of trying to amend the bill. He said "You would have been hopelessly involved and you would have lost if you had tried to amend that bill; you were wise not to do so." That happens to be an expression from one of the senators on the subcommittee. This is a complicated question. The American Medical Association cannot write a bill and cannot present a bill tagged as a bill of the American Medical Association. We have a positive platform. We must have a definite understanding with Dr. McCormack, Dr. Underwood and many of our friends who are public health men. From a personal standpoint, there should be men in the Senate that we know, or men in the House of Representatives that we know—that some of you know—who think along the same lines as we think, who appreciate the platform as a good document, sound Americanism and sound in policy. Some of them ought to be able to write a bill that would reflect the principles in which we believe.

DR. A. T. McCORMACK, Louisville, Ky.: I think I feel with you, especially those of you who have had any experience in legislative matters, an entirely hopeful attitude as a result of the splendid statement of principles that has been presented to us this morning. It is natural for us as a profession to be conservative. We know tried methods in medicine. We know that the practice of medicine in the United States has been successful in giving us the best health conditions and the best medical service that there is on the globe. Our objective is to do some of the things that have been left undone and do them in some of the spots which have not yet received the beneficence of our science. Legislation is going to be proposed. You have here the principles adopted and specific instructions as to what the amendments should be to make it conform to these principles. We can go to the American people with these principles and secure their support for them because they are constructive. If we really and seriously mean that we are for legislation that will effectuate these purposes, then we can win any fight in Congress. I don't think there is any question that we can defeat the Wagner bill at any time. I think it would have defeated itself if enough members of Congress had ever read it, because it was hopelessly impossible. It couldn't have been administered. It couldn't have been operated. It would have been a futile expenditure of money and would have caused irreparable damage and loss of impetus to the whole public health and the whole medical service. Here today we have again established ourselves firmly on the basis and foundation of a program that is right. Let's stick to it. Each of us is a secretary of a state medical association. In your state, if your health department doesn't conform to your policies, it is the fault of the state medical association of your state because it hasn't done anything about it. If your medical profession wants to control public health policies in your state, all you have to do is to assume that control. Every now and then I hear somebody say that the health officers of this country are going to dominate the American Medical Association. There are four of us in the House of Delegates and there never have been five even when West used to be there as state health officer. During that time our average brain power was much higher than it is now.

DR. HOLMAN TAYLOR, Fort Worth, Texas: I want to make inquiry of those in charge as to the nature or character of the distribution of the results of this survey of medical services. Anticipating a demand, we have sought to make up 100 packages on the subject of socialized medicine. Among these packages we have been seeking to place the results of this survey. In Texas, schools are mainly interested in what the conditions are

in Texas. To those who make inquiry on the subject we have a little summary our office made of the survey that was made in Texas. Will these reports be so distributed that those of us who want them can get a reasonably large number of copies for distribution? Concerning the eight points, I want to acclaim those as a fine statement of principles. I think it would be good if we could work in here, perhaps under 5, attention to the fact that a man is not medically indigent until he is not able to buy medical service, and the facts in the case must be determined locally and not nationally.

DR. OLIN WEST, Chicago: There were all sorts of groups that participated in the surveys in the individual states, including physicians, dentists, pharmacists, nurses, public officials, hospital administrators and staffs and civic clubs. In most instances the conclusions arrived at by the representatives of these various groups were exactly the same. Pharmacists, social service workers, civic clubs, health officers, public officials agreed in many of the items covered by this survey. We hope to have this report soon available. I don't know how big a volume it will be, but I do want to say to you that in case of need we

shall try to provide you with something that may be helpful to you. If we can provide you with the whole report, we shall try to do that.

DR. W. C. WOODWARD, Chicago: A question was asked as to amendments. I want to emphasize that the proper way to propose a proposed bill or proposed amendment would be for those who are interested to sit around a table and talk the matter over and agree as far as they can agree, and agree to disagree where they cannot agree, and go before Congress in that way. The difficulty is that the opposition in this case, if I may call it the opposition, is apparently doing everything it can to prevent a conference of this sort. I have before me a copy of the program of the American Association for Labor Legislation which is to meet in Philadelphia December 27, 28 and 29. I find that James E. Murray, United States Senator from Montana, chairman of the Hearing Committee on the Health Bill, is to talk on the latest proposals for a National Health Program. It is obvious that he is going to have some information assembled before the 28th.

(To be continued)

OFFICIAL NOTES

THE NEW YORK SESSION

Special Features Authorized for the Scientific Exhibit

Several features have been authorized by the Committee on Scientific Exhibit for the New York session:

Special Exhibit on Fractures under auspices of a committee composed of Dr. Kellogg Speed, chairman, Chicago; Dr. Frank D. Dickson, Kansas City, Mo., and Dr. Walter Estell Lee, Philadelphia.

Special Exhibit on Lamé Backs under the auspices of a committee composed of Dr. Frank R. Ober, chairman, Boston; Dr. Carl E. Badgley, Ann Arbor, Mich.; Dr. J. Archer O'Reilly,

St. Louis; Dr. Arthur Steindler, Iowa City, and Dr. Philip D. Wilson, New York.

Special Exhibit on Fresh Pathology under the auspices of a committee of which Dr. Harrison S. Martland, Newark, N. J., is chairman.

Exhibit symposiums on heart disease and peripheral vascular disease, under the guidance of committees headed by Dr. Thomas M. McMillan, Philadelphia, and Dr. Norman E. Freeman, Philadelphia.

In addition to the foregoing, the usual exhibits in conjunction with the fifteen sections of the Scientific Assembly will be shown. Applications for space will close February 1. Application blanks may be obtained from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

WOMAN'S AUXILIARY

California

At the autumn meeting of the auxiliary to the Los Angeles County Medical Association in Los Angeles Dr. George D. Maner discussed pending legislation of interest to the medical profession.

Mrs. Frederick N. Scatena, president, auxiliary to the California Medical Association, addressed the auxiliary to the Marin County Medical Society in Fairfax recently on the history of the auxiliary.

Georgia

An auxiliary to the Fourth District Medical Society was organized at a recent meeting in La Grange. Mrs. Kenneth Grace was elected president. Mrs. Eustace A. Allen, president of the auxiliary to the Medical Association of Georgia, addressed the group on the aims and objectives of the auxiliary.

The auxiliary to the Tift County Medical Society was organized recently in Tifton. Mrs. C. A. Fleming was elected president.

At the September meeting of the auxiliary to the Fulton County Medical Society in Atlanta Dr. Wadley Glenn reported on his recent world tour, and Dr. Edgar H. Greene, president of the Fulton County Medical Society, told of plans for the new building for the society. At the October meeting of the auxiliary Dr. Jack Norris spoke on "Milk in Relation to Health," and Mrs. W. M. Dunn presented material selected from *Hygeia*.

The semiannual meeting of the auxiliary to the Fifth District Medical Society was held at the Academy of Medicine in Atlanta October 5. Dr. George H. Semken, New York, spoke on "Women's Interest in Cancer," and Dr. William H. Myers, president of the Medical Association of Georgia, spoke on "Solving the Cancer Problem."

Kansas

The chief objective of the auxiliary to the Shawnee County Medical Society this year is to increase subscriptions to *Hygeia*.

Mrs. Frank E. Coffey, chairman of the printing and supplies committee of the auxiliary to the American Medical Association, was speaker at a meeting of the auxiliary to the Central Kansas Medical Society in Hays recently.

Mrs. C. D. Korsar, chairman of the Hygeia Committee of the auxiliary to the Kansas Medical Society, was speaker at the autumn meeting of the auxiliary to the Cloud County Medical Society in Concordia.

New York

The second annual Health Institute of the auxiliary to the Medical Society of the County of Kings was held in Brooklyn October 10. Speakers were Dr. Philip I. Nash, president of the Medical Society of Kings County; Dr. Charles Solomon, chairman, subcommittee on food and drugs of the Public Health Committee; Dr. Walter Bromberg, psychiatrist in charge, Court of General Sessions, New York City Police Department; Dr. Adele Streeseiman, chairman, Advisory Council to the Woman's Auxiliary of Kings County Medical Society; Dr. Jean A. Curran, Long Island College of Medicine; Dr. Herbert R. Edwards, director, tuberculosis division, department of health; Dr. Thomas A. McGoldrick, medical director, St. Anthony's Hospital; Dr. Foster Murray, director of tuberculosis, Kingston Avenue Hospital, and Dr. Eugene R. Marzullo, chairman, Public Health Committee. The Health Institute was presented by the auxiliary as its contribution toward health education. Representatives of the board of health and the Brooklyn Tuberculosis and Health Association presented exhibits and demonstrations.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Personal.—Dr. Ceasar G. Cahen, for twenty-seven years chief surgeon of the French Hospital, Los Angeles, was presented with a diploma November 4 designating him chief consulting surgeon of the hospital for life.—Dr. Ruggles A. Cushman, Cloverdale, has been granted a retired membership in the California Medical Association.

Society News.—Dr. Joel J. Pressman showed a motion picture study of the larynx before the Los Angeles Society of Ophthalmology and Otolaryngology at a meeting December 18; Drs. Isaac H. Jones and William T. Grant discussed "The Elsberg Precision Measurements of the Sense of Smell."—Among others, Dr. Ernest M. Hall spoke before the Los Angeles Heart Association December 13 on "Etiology of Calcified Nodular Aortic Stenosis."

CONNECTICUT

Dr. Putnam Lectures on Epilepsy.—Dr. Tracy J. Putnam, director of services of neurology and neurosurgery, the Neurological Institute of the Columbia-Presbyterian Medical Center, New York, delivered the second annual lecture to be given before the faculty and students at Yale University School of Medicine, New Haven, December 1, under the auspices of the Yale chapter of Nu Sigma Nu. His subject was "Modern Concepts of Epilepsy and Its Treatment."

DELAWARE

Society News.—Dr. Edward H. Richardson, associate professor of gynecology at the Johns Hopkins University School of Medicine, Baltimore, addressed the New Castle County Medical Society, Wilmington, November 21 on "Use of Hormones in Gynecology."

DISTRICT OF COLUMBIA

Director of Venereal Disease Control.—Dr. George M. Leiby, Raleigh, for the last three years director of the division of venereal disease control of the North Carolina State Department of Health, has been appointed as the first full time director of the venereal disease service for the District of Columbia.

Society News.—Dr. Jesse G. M. Bullowa, New York, addressed the George Washington University Medical Society October 21 on "The Doctor's Responsibility to Pneumonia Patients."—At a meeting of the Georgetown Clinical Society November 21 Dr. Harry Zehner spoke on "Cardiology."—Dr. Norvell Belt discussed "Testicular Tumor with Endocrine Disturbance" before the Clinical Club of Washington November 7.—Among the speakers before the Washington Society of Pathologists at the Army Medical Museum recently were Drs. Virgil H. Cornell on "Undifferentiated Small Cell Carcinoma of Small Intestine" and George Tolstoi, "Granulosa Cell Tumor of the Ovary."—Included among the speakers before the Washington Ophthalmological Society November 6 was Dr. John W. Burke on "Field Changes Following Satisfactory Filtration Operation for Glaucoma."—Dr. Walter E. Dandy, Baltimore, addressed a meeting of the medical and dental officers of the navy on duty in the District and vicinity at the Naval Medical School December 4 on "Head Injuries."

GEORGIA

Jonte Eguen Memorial Lecture.—Dr. Harris P. Mosher, emeritus professor of laryngology and Walter Augustus Leconte professor of otology, Harvard Medical School, Boston, will deliver the third Jonte Eguen Memorial Lecture in Atlanta January 26 before the Fulton County Medical Society.

New Chair of Surgery.—The endowment of the J. B. Whitehead chair of surgery at Emory University School of Medicine has been announced in the *Bulletin* of the Fulton County Medical Society. The new position was made possible by the gift of \$250,000 by the Joseph B. Whitehead Foundation.

Special Society Elections.—Dr. John L. Elliott, Savannah, was elected president of the Georgia Tuberculosis Association at its annual meeting in Alto in November.—At a meeting of the Georgia Industrial Surgeons' Association recently in Brunswick Dr. Robert L. Rhodes, Augusta, was chosen president; Dr. Richard E. Newberry, Atlanta, vice president, and Dr. John W. Simmons, Brunswick, secretary-treasurer.

Society News.—At a meeting of the Macon Medical Society of Bibb County in Macon recently Dr. Milford B. Hatcher, Macon, discussed "Treatment of Burns with Skeletal Support in Severe and Extensive Burns of the Lower Extremity."—Dr. Julian K. Quattlebaum read a paper entitled "Cancer of the Stomach" before the Georgia Medical Society in Savannah recently and Dr. Elzie N. Gleaton presented a case of "Sarcomatosis in a Baby One Month Old."—Dr. Joseph H. Boland gave a clinical talk on football injuries before the Fulton County Medical Society, Atlanta, November 16 and Drs. Carter Smith and Henry C. Sauls discussed "Coronary Occlusion—A Clinical and Electrocardiographic Study of 100 Patients." All are from Atlanta.

ILLINOIS

Personal.—Dr. Paul H. Harmon, formerly director of the crippled children's bureau for the state department of welfare of Illinois and instructor in orthopedic surgery at the University of Chicago, has been appointed to the staff of the Guthrie Clinic and Robert Packer Hospital, Sayre, Pa., as orthopedic surgeon, effective January 1.

Stop-and-Go Lights at Postgraduate Conference.—At a postgraduate medical conference in Champaign December 7 an ingenious device was used to assist speakers in staying within the twenty minutes allotted for papers. A stop-and-go light on the table showed green as the speaker began his address, turned yellow when three minutes was left and red when the twenty minutes was at an end. The apparatus was made by local men and, according to the secretary of the state medical society, Dr. Harold M. Camp, Monmouth, it is recommended for keeping speakers from running over specified time limits. The Champaign conference was the second in a series sponsored by the state medical society; 208 physicians representing sixty-five cities and towns in thirty counties attended.

Chicago

Dr. Heiser to Give Public Lecture.—Dr. Victor G. Heiser, New York, will address the next public meeting of the Chicago Medical Society January 3 at the Chicago Woman's Club, on "Will There Be Another Smallpox Epidemic?"

Society News.—At a meeting of the Chicago Gynecological Society December 15 the speakers included Drs. Ralph E. Campbell, Madison, Wis., on "Angular Pregnancy"; Louis Rudolph, "Pseudo-Uterus Bicornis," and Morris Edward Davis, "Stilbestrol, a New Synthetic Organic Estrogen: A Clinical Study."

Society Branch Meetings.—At a meeting of the North Shore Branch of the Chicago Medical Society December 5 Dr. William Barry Wood Jr., Boston, spoke on "Treatment of Pneumococcal Pneumonia." Dr. Howard K. Gray, Rochester, Minn., addressed the North Side Branch December 7 on "Problems Associated with Surgery of the Biliary Tract." The Evanston Branch was addressed December 7 by Dr. Henry C. Sweany on "Pathogenesis of Tuberculosis, Municipal Tuberculosis Sanitarium."

INDIANA

Study of Hunting Accidents.—With a view to reducing hunting accidents, a survey of these accidents is being made under the direction of Virgil M. Simmons, commissioner of the state department of conservation. Game wardens have been provided with special forms and will call on physicians in an effort to assemble data on persons whom they have treated who have been involved in hunting accidents. Questions included in the forms cover such subjects as the nature and results of the injuries sustained, type of firearms involved, style and color of various articles of clothing worn, whether the accident occurred under heavy cover or in open fields, whether the accident involved more than one person and a statement explaining how the accident occurred. The study has been undertaken as a means of determining the major hazards of hunting.

Society News.—A symposium on diseases of metabolism was presented before the Indianapolis Medical Society November 28 by Drs. William E. King, James O. Ritchey, Marion R. Shafer, Brandt F. Steele and Harold F. Dunlap. The

society was addressed by Dr. James S. McLester, Birmingham, November 7; his subject was "Nutrition and Present Day Living." Drs. Edwin W. Dyar Jr., Robert M. Dearmin and Russell A. Sage discussed "Head and Face Pain from the Standpoint of Ophthalmology and Otolaryngology" before the society December 19. Dr. Edward C. Rosenow, Rochester, Minn., addressed the society December 12 on "Experimental and Clinical Studies on the Relation of Streptococci to Various Diseases."—Dr. William B. Tucker, Chicago, addressed the Tippecanoe County Medical Society in Lafayette October 17 on "Primary Carcinoma of the Lungs."—Dr. Carl P. Huber, Indianapolis, discussed "Bleeding in Pregnancy and Labor" before the Northeastern Indiana Academy of Medicine in Kendallville November 16.—Dr. Henry J. John, Cleveland, addressed the Muncie Academy of Medicine November 14 on "Diabetes and the Relation to It of Some Metabolic Diseases." Weston A. Price, D.D.S., Cleveland, addressed the academy December 12 on "Nutrition and Modern Degeneration, Physical, Mental and Moral."—The LaPorte County Medical Society was addressed in Michigan City November 16 by Dr. Arthur Earl Walker, Chicago, on "Early Manifestations of Intracranial Lesions."—At a meeting of the Gibson County Medical Society in Princeton November 13 Dr. Max Cutler, Chicago, discussed the diagnosis and treatment of cancer.—The Wayne-Union Counties Medical Society was addressed in Richmond November 9 by Dr. Richard M. Davison, Chicago, on "Surgical Treatment in Pulmonary Tuberculosis."

IOWA

Personal.—Dr. James Frederic Clarke, Fairfield, was honored at a banquet given by the Jefferson County Medical Society November 9 in recognition of his completion of fifty years in the practice of medicine.—Dr. Edwin N. Hesbacher, formerly of Minneapolis, has been placed in charge of the Polk County health unit.

KANSAS

Personal.—Dr. Harry W. Davis, Plains, was recently appointed health officer of Meade County.—Dr. Charles F. Menninger, Topeka, was recently made an honorary member of the Shawnee County Medical Society in observance of his completion of fifty years in the practice of medicine.

Society News.—At a meeting of the Butler-Greenwood County Medical Society in El Dorado recently Dr. Ralph L. Drake, Wichita, discussed brain tumors.—Dr. John L. Lattimore, Topeka, addressed the Clay County Medical Society in Clay Center recently on "Newer Laboratory Methods and Their Interpretation."—Dr. Benjamin P. Smith, Neodesha, discussed diabetes before the Wilson County Medical Society at a meeting in Neodesha recently.—At a meeting of the Wyandotte County Medical Society, Kansas City, December 19 the speakers included Drs. Thomas G. Orr, Kansas City, Mo., and Galen M. Tice, Kansas City, on "Carcinoma of the Breast."—The Sedgewick County Medical Society was addressed in Wichita, November 21 by Dr. Edward H. Hashinger, Kansas City, Mo., on "Causes and Treatment of Obesity" and November 7 by Drs. Christian A. Hellwig and Frank L. Menehan, Wichita, on "Coronary Sclerosis" and "Embryoma of the Kidney" respectively.

KENTUCKY

District Meeting.—The fifth and tenth councilor districts held a joint meeting in Frankfort December 13 with the Franklin County Medical Society as host. At an afternoon session Drs. John Harvey, Lexington, and DeLou P. Hall, Louisville, presented papers on "Sulfapyridine in the Treatment of Pneumonia" and "Carcinoma of the Colon" respectively. In the evening Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, made an address on "American Medicine and the National Government" under the auspices of the county society and the Frankfort Forum Club.

Society News.—Dr. Vilray P. Blair, St. Louis, addressed the Jefferson County Medical Society, Louisville, November 20 on "Treatment of Cancer of the Face."—Dr. Kenneth W. Brumback, Cynthia, addressed the Harrison County Medical Society, Cynthia, November 6 on "Diagnosis and Treatment of Lobar Pneumonia."—Dr. Arthur T. McCormack, Louisville, addressed the Boyle County Medical Society, Danville, December 19 on "Medical Social Security."—Drs. Milton S. Lewis, Nashville, and George E. Pryor Jr., Hopkinsville, addressed the Christian County Medical Society in Pembroke November 14 on "Diagnosis and Management of the Posterior

Position" and "Diagnosis and Management of the Goiter Case" respectively.—At a meeting of the Muldraugh Hill Medical Society in Elizabethtown December 14 the speakers were Drs. Harry S. Andrews, Louisville, on "Recent Methods of Treating Pneumonia"; John W. Fish, Louisville, "Common Eye Injuries, Their Diagnosis and Treatment"; Clyde C. Carroll, White Mills, "Differential Diagnosis of the Acute Exanthemata," and John M. English, Elizabethtown, "Ethics of the Medical Profession."—Drs. William N. Lipscomb and Rufus C. Alley, Lexington, addressed the Bourbon County Medical Society, Paris, November 16 on "Anemias of Childhood" and "Practical Management of Rectal Abscesses and Fistulae" respectively.

LOUISIANA

Personal.—Dr. William K. Evans, Lake Providence, has been appointed health officer of West Carroll Parish, succeeding Dr. William J. Buffalo, Oak Grove, who resigned to engage in private practice in North Carolina, it is reported.

MARYLAND

Society News.—At a joint meeting of the Medical Society of the District of Columbia and the Baltimore City Medical Society December 1 in Baltimore the speakers were Drs. Wallace M. Yater, Washington, D. C., on "Pathogenesis and Prognosis of Bundle Branch Block" and Thomas Bradley, Washington, D. C., "Management of Intractable Pain."

Medical Board for Occupational Diseases.—The governor recently appointed a state medical board for occupational diseases with the following members: Drs. Raymond Hussey, chairman, Nathan B. Herman and John W. Pierson, all of Baltimore. The creation of the board was provided for in the new state occupational disease law regulating compensation in this field.

Seminars on Industrial Hygiene.—The committee on industrial health of the Medical and Chirurgical Faculty of Maryland has recently inaugurated a series of sixteen seminars on industrial hygiene. The series opened with introductory remarks October 25 by Dr. Carl M. Peterson, Chicago, Secretary of the Council on Industrial Health of the American Medical Association. Dr. John M. McDonald, director of the bureau of occupational diseases of the Baltimore health department, spoke on "Occupational Health Hazards of the Industries in Maryland." Other speakers included:

Theodore C. Waters, Baltimore attorney, October 31, The Formulation of Occupational Disease Legislation.

Henry D. Sayer, former commissioner of industrial diseases of the state of New York, November 7, The Operation of a State Industrial Commission.

Thomas N. Bartlett, manager, claim division, Maryland Casualty Company, Baltimore, November 21, The Insurance Aspects of Compensation for Occupational Diseases.

Walter F. Perkins, vice president, Koppers Company, Bartlett Hayward Division, Baltimore, December 5, Industrial Health: An Employer's Point of View and Attitude.

John P. Frey, president, metal trades department, American Federation of Labor, Washington, D. C., December 19, Industrial Health: The Employee's Point of View.

The program for January, February and March is not yet available. It is planned to give attention to the hazards of carbon monoxide and dusts and to the general problems of preventing and controlling the occupational diseases.

MASSACHUSETTS

Personal.—Dr. Clarence G. Lane has been promoted to be clinical professor of dermatology at Harvard Medical School and Dr. Francis R. Dieuaide to be associate professor of medicine.—Dr. Frank M. Vaughan, Boston, was recently appointed a member of the state board of registration in medicine.

Free Public Lectures.—A series of free public lectures on medical subjects will begin January 7 at Harvard Medical School. Lecturers include the following members of the faculty:

Dr. Chester M. Jones, January 7, Digestion and Indigestion.
Dr. Charles C. Lund, January 14, Serious Accidents—What to Do and What Not to Do.

Dr. Chester S. Keefer, January 21, What About Sulfanilamide?

Dr. Perry C. Baird Jr., January 28, Care of the Complexion.

Dr. Paul D. White, February 4, Facts and Fancies About Heart Disease.

Dr. Grantley W. Taylor, February 11, Cancer.

Gerry B. Schnelle, February 18, The Medical Care of Domestic Pets.

Dr. Donald Macomber, February 25, Sterility (for women only).

Dr. Frank R. Ober, March 3, Backache.

Dr. William B. Breed, March 10, Health in Middle Age.

MICHIGAN

Honored at One Hundred.—Dr. John McLean, Hartford, was honored at a banquet November 14 by Masons of southwestern Michigan in observance of his one hundredth birthday. Dr. McLean graduated at Northwestern University Medical School, Chicago, in 1873 and was licensed to practice in Michigan in 1902.

Special Society Elections.—Dr. James A. Olson, medical director for the public schools of Flint, was elected president of the Michigan School Health Association at a recent meeting in Grand Rapids. —Dr. Mark F. Osterlin, medical superintendent of the Central Michigan Children's Clinic, Traverse City, was chosen president of the Michigan Pediatric and Infectious Disease Society at its annual meeting in Ann Arbor November 25; Dr. Campbell Harvey, Pontiac, was made vice president, and Dr. David M. Cowie, Ann Arbor, was reelected secretary.

Society News.—Dr. Henry Field Jr., Ann Arbor, discussed "Subclinical Pellagra in Michigan" before the Wayne County Medical Society, Detroit, December 11. A joint meeting with the Detroit Physiological Society was addressed December 18 by Clarence A. Mills, Ph.D., Cincinnati, on "Climatic and Weather Information on Health." —Dr. Raymond W. Waggoner, Ann Arbor, addressed the Genesee County Medical Society in Flint December 6 on "The Organic Background for Psychoses and Neuroses." —Dr. Orus R. Yoder, Ypsilanti, discussed "Psychologic Management of the Patient" before the Jackson County Medical Society November 21. —Dr. Evan V. Shute, London, Ont., discussed "Use of Endocrine Products in Gynecology and Obstetrics" before the Kalamazoo Academy of Medicine November 21.

MINNESOTA

Radiologic Meeting.—The Minnesota Radiological Society held its fall meeting at the Mayo Clinic, Rochester, December 2. Included on the program were the following:

- Drs. Clarence A. Good Jr. and Arthur B. Hunt, Experiences with Roentgenologic Pelvimetry.
- Dr. Harry M. Weber, The Proctosigmoiditis of Lymphogranuloma Venereum.
- Drs. John A. L. McCullough and John D. Camp, Pseudo-Fractures in Diseases Affecting the Skeletal System.
- Dr. Everett E. Seedorf, The Evaluation of Prostigmine, Barium Chloride, Oxygen and Pitressin for the Elimination of Flatus, in Roentgenograms of the Abdomen.
- Dr. Stuart W. Harrington, Intrathoracic Tumors.

A symposium on primary carcinoma of the lung was presented by Drs. John W. Olds, Edgar H. Little and Eugene T. Leddy and in the evening at dinner Dr. Harry M. Worth discussed "Radiology in England" and Dr. Shao-hsun Wang, "The Practice of Medicine in China."

Society News.—At a meeting of the Minnesota Academy of Medicine in St. Paul November 8 Dr. Gilbert J. Thomas, Minneapolis, spoke on "Genital Tuberculosis." —Walter J. Meek, Ph.D., Madison, Wis., discussed "Effects of the General Anesthetics and Sympathomimetic Amines on Cardiac Automaticity" in a Mayo Foundation lecture in Rochester November 16. —The Hennepin County Medical Society devoted its meeting in Minneapolis November 29 to a symposium on headache; the speakers were Drs. Gordon R. Kamman, St. Paul; George E. McGeary, Lawrence R. Boies and Reuben A. Johnson. A symposium on joint injuries and their associated problems was presented before the society November 22 by Drs. Edward T. Evans, Miland E. Knapp and John H. Moe. —At a meeting of the Minnesota Pathological Society in Minneapolis December 19 the speakers were Drs. Charles E. Rea on "Present Day Concept of the Undescended Testis" and Nathaniel H. Lufkin, "The Myocardium in a Case of Myxedema."

NEW JERSEY

Health Association Meeting.—Dr. Leverett D. Bristol, Montclair, was elected president of the New Jersey Health and Sanitary Association at the annual meeting in Asbury Park November 17-18. Dr. Edward Guion, Northfield, was elected secretary.

Society Plans Exhibit for the Public.—The public relations committee of the Essex County Medical Society announces an "Exhibit for the Laity" to be held February 5-10, to acquaint the public with various phases of medical care and treatment. Thirty-three separate exhibits have been planned. Among them are fractures and industrial medicine, crime detection, cancer, pneumonia, venereal disease, hay fever, transfusions, necropsies, tuberculosis, a model operating room, eye conservation, medical history. The Essex County Dental Society and the

New Jersey Pharmaceutical Association have been invited to present appropriate exhibits also. A program of evening lectures is being planned as part of the program.

Society News.—Dr. William Wolf, New York, addressed the Atlantic County Medical Society, Atlantic City, December 8 on "Procedures Common in Endocrinology." —Dr. Priscilla White, Boston, discussed diabetes in an address before the Camden County Medical Society, Camden, December 5. —Dr. Frank L. Meleney, New York, addressed the Academy of Medicine of Northern New Jersey, Newark, December 21 on septicemia. —Dr. Edwin H. Place, Boston, addressed the Hudson County Medical Society, Jersey City, December 5 on "Experiences in Diagnosis and Treatment of the Acute Infectious Diseases." —Dr. Manfred Kraemer, Newark, was elected president of the New Jersey Gastroenterological Society at the annual meeting December 4; Dr. Hyman I. Goldstein, Camden, vice president, and Dr. Sydney Rosenthal, Newark, secretary. —A program on pneumonia was presented before the Bergen County Medical Society, Hackensack, December 12 by Drs. Wheelan D. Sutliff, Norman H. Plummer and Charles Hendee Smith, all of New York.

NEW YORK

Society News.—Dr. George B. Eusterman, Rochester, Minn., addressed the Geneva Academy of Medicine at its annual dinner meeting November 16 on "Nonsurgical Aspects of Certain Acute Abdominal Conditions." Drs. William S. McCann, Rochester, and Samuel A. Munford, Clifton Springs, were guests who discussed the paper. —Dr. Ralph S. Bromer, Bryn Mawr, Pa., addressed the Schenectady County Medical Society, Schenectady, November 7 on "Roentgenologic Skeletal Changes in the Diseases of Infants and Children." —Dr. Henry C. Sweany, Chicago, addressed the Nassau County Medical Society, Garden City, November 28 on "What the Doctor Should Know About Tuberculosis."

Dr. Ross Honored.—The Suffolk County Medical Society gave a dinner November 25 at Smithtown honoring Dr. William H. Ross, Brentwood, in recognition of his fifty years of medical practice. Tributes were paid to Dr. Ross by Drs. Terry M. Townsend, New York, president of the Medical Society of the State of New York; Peter Irving, New York, secretary of the state society; Alec N. Thomson, Brooklyn, editor of the *Bulletin of the Medical Society of the County of Kings*; Frank Overton, Patchogue, editor of the *Journal of the Medical Society of New Jersey*; Arthur D. Jaques, Lynbrook, president of the Associated Physicians of Long Island, and Willetts W. Gardner, Patchogue, president of the Suffolk County society. Dr. Ross, who is 77 years old, has been president of the state medical society, the Associated Physicians of Long Island, the Suffolk County society and the New York Association of Superintendents and Managers of Tuberculosis Sanatoria, among other offices.

New York City

Investigation of Salmonella.—A center for the investigation of Salmonella has been established at Beth Israel Hospital, Stuyvesant Park East, under the direction of Dr. Friedrich Schiff of the department of bacteriology. The center is willing to investigate without charge doubtful cultures for Salmonella. The work is being done in cooperation with the International Salmonella Center in Copenhagen, Denmark.

Friday Afternoon Lectures at the Academy.—The Friday Afternoon Lectures at the New York Academy of Medicine during January and February will be as follows:

- Dr. Yale Kneeland Jr., Primary Bronchopneumonia, January 5.
- Dr. Donovan J. McCune, Recent Advances in the Clinical Use of Vitamin D and Related Compounds, January 12.
- Dr. Martin Henry Dawson, Treatment of Chronic Arthritis, January 19.
- Dr. James Burns Amberson Jr., Choice of Treatment for Pulmonary Tuberculosis with Special Reference to Newer Surgical Procedure, January 26.
- Dr. Carl H. Smith, Management of the Anemias in Infancy and Childhood, February 2.
- Dr. George Gray Ward, Recent Advances in Gynecology, February 9.
- Dr. George M. MacKee, Recent Advances in Dermatology, February 16.

New Directors of Hospital Service Plan.—Seven new directors have been added to the board of Associated Hospital Service of New York, five representing the medical profession and two the administrators of hospitals. The physicians, appointed from a list submitted by the county medical societies in the metropolitan area, are Drs. John J. Masterson, Brooklyn; Milton J. Goodfriend, Charles Gordon Heyd, New York; Joseph Wrana, Jamaica, and Eric H. G. Restin, Mount Vernon. The hospital administrators are Drs. Joe R. Clemmons, New York, and George O'Hanlon, Jersey City, N. J.

Society News.—Speakers at a stated meeting of the New York Academy of Medicine December 7 on disorders of the venous and lymphatic systems were Drs. Cecil K. Drinker, Boston, on "Participation of the Lymphatics in Acute and Chronic Inflammations"; Bayard T. Horton, Rochester, Minn., "Clinical Aspects with Respect to the Venous System," and Gerald H. Pratt, "Surgical Considerations."—Speakers before the New York Roentgen Society December 18 included Drs. Samuel J. Goldfarb, Burrill B. Crohn, David Adlersberg and Marcy Lee Sussman, who presented a symposium on the small intestine.—Dr. Sara M. Jordan, Boston, gave a Friday afternoon lecture before the Medical Society of the County of Queens November 17 on medical aspects of gastric disease.—Dr. William S. Collens gave a Friday afternoon lecture of the Medical Society of the County of Queens December 15 on "Organic Peripheral Vascular Disease."—The New York Academy of Medicine announces that dates for the Thirteenth Graduate Fortnight will be Oct. 14-25, 1940.

Hospital Celebrates Seventy-Fifth Anniversary.—The Hospital for Ruptured and Crippled marked its seventy-fifth anniversary with a dinner November 2 at the University Club. Speakers who discussed various phases of the hospital's work and history were:

Dr. Fenwick Beckman, attending surgeon at the hospital.
Dr. George E. Bennett, associate professor of orthopedic surgery, Johns Hopkins University School of Medicine, Baltimore.
Dr. William E. Gallie, dean, University of Toronto Faculty of Medicine, Toronto, Ont.
Dr. Robert B. Osgood, professor emeritus of orthopedic surgery, Harvard Medical School, Boston.
Dr. Eugene H. Pool, clinical professor of surgery, Cornell University Medical College and Columbia University College of Physicians and Surgeons.
Dr. Paul C. Colonna, professor of orthopedic surgery, University of Oklahoma School of Medicine, Oklahoma City.
Dr. Philip D. Wilson, clinical professor of orthopedic surgery at Columbia and surgeon in chief at the hospital.

To mark the anniversary Dr. Beckman has written a 157 page history of the hospital, which has grown from an institution accommodating twenty-eight persons to its present capacity of 250 beds.

New Dean at New York Medical College.—Other Faculty Changes.—Dr. Ferdinand C. Lee, associate professor of surgery, Johns Hopkins University School of Medicine, Baltimore, has been appointed dean of New York Medical College, Flower and Fifth Avenue Hospitals. Dr. Lee will also be professor and head of the department of surgery. He succeeds as dean Dr. Claude A. Burrett, who has been made president of the college and hospitals. Dr. J. A. Werner Hetrick has been appointed associate dean and Mr. David Q. Hammond, director of the hospitals. Other appointments to the faculty include:

Dr. Thomas I. Hoeh, recently head of the department of neurosurgery and neurology at St. Luke's and St. Mary's hospitals in Montreal, Canada, professor of neurosurgery and head of the department of neurosurgery and neuropsychiatry.
Dr. Richard Townley Paton, recently surgeon on the staff of the Manhattan Eye, Ear and Throat Hospital, professor and head of the department of ophthalmology.
Dr. William H. Everts, who took the degree of doctor of medical sciences at Columbia University College of Physicians and Surgeons in 1936 and received later training in the New York Neurological Institute, professor of neurology.

NORTH CAROLINA

Hospital News.—The cornerstone of a new building for the Presbyterian Hospital, Charlotte, was laid November 15. The Duke Endowment contributed \$150,000 toward the new building. The present hospital will be remodeled for a nurses' home.

Society News.—Dr. Franklin Webb Griffith, Asheville, addressed the Buncombe County Medical Society, Asheville, December 4 on "Urgent Surgery on Infants."—Speakers at a meeting of the Catawba Valley Medical Society, Lenoir, November 14, were Drs. Ernest Washington Franklin Jr., Charlotte, on "Traumatic Postpartum Hemorrhage"; Frederick Mast Dula, Lenoir, "Diagnosis of Appendicitis," and Yates Shuford Palmer, Valdese, "Treatment of Lower Extremity Varicose Veins by Ligation and Injection."

PENNSYLVANIA

Society News.—Dr. Frederick M. Jacob, Pittsburgh, addressed the Westmoreland County Medical Society December 19 at the Mountain View Hotel near Greensburg on "Inflammatory Diseases of the Skin—Eczema, Psoriasis, Hives (Erythemas)."—Drs. Edward F. Hartung, New York, and Francis C. Grant, Philadelphia, were guest speakers at the semiannual clinic meeting of the Lycoming County Medical Society, Williamsport, November 10, on "Rheumatoid Arthritis" and "Diagnosis and Treatment of Cerebral Lesions" respectively.

WEST VIRGINIA

Council Approves Platform.—The council of the West Virginia Medical Association at a meeting in Charleston December 14 adopted a resolution approving the recommendation of the American Medical Association for a federal department of health with a physician as head. The resolution also expressed approval of the entire platform recently set forth by the Board of Trustees of the Association.

GENERAL

Sectional Meeting on Ear, Nose and Throat.—The Eastern section of the American Laryngological, Rhinological and Otological Society will hold its annual meeting in Pittsburgh January 5. The speakers will include Drs. Francis W. Davison, Danville, Pa., on "Acute Laryngotracheobronchitis"; Carl H. McCaskey, Indianapolis, "Etiology and Treatment of Seventh Nerve Paralysis"; James G. Dwyer, New York, "Present Status of Otitic Meningitis," and Fred W. Dixon, Cleveland, "Practical Points in the Treatment of Sphenoiditis."

Changes in Status of Licensure.—The Indiana State Board of Medical Registration and Examination reports the following:

Dr. Joseph _____ license revoked November 16.
Dr. Harry _____ revoked November 16 because of admitted _____ of rendering him unfit for practice.
Dr. Scott R. Edwards, New York, license revoked November 16 because of admitted drug addiction to the extent of rendering him unfit for practice.

The Kansas Board of Medical Registration and Examination announces the following:

Dr. John R. Clark, Independence, license revoked June 13 for gross immorality, having been convicted of a felony.
Dr. Charles C. Keester, Wichita, license restored June 27.

The Massachusetts Board of Registration in Medicine reported the following:

Dr. David H. Shulman, Brookline, license restored August 18.

The Washington state department of licenses reports the following action:

Dr. Edna V. Dale, whose last known address was Yakima, license revoked recently for violation of the narcotic laws.

Progress of Venereal Disease Control.—Every state and territorial health department in the United States had a separate division or subdivision for control of venereal diseases by the end of the fiscal year 1939, the U. S. Public Health Service reports. In 1938 twenty-seven states were so organized. About 103,000 persons were discharged from clinics as cured or with syphilis arrested in 1939 as compared with 78,000 in 1938, the report continued. Persons brought under treatment for the first time numbered 315,000 and the number of treatments administered was 8,000,000. Nineteen states now require examinations including blood tests for syphilis of all applicants for marriage licenses and fifteen require physicians to perform blood tests for syphilis on expectant mothers. In 1939 2,405 venereal disease clinics reported to the public health service, an increase of 37.7 per cent over 1938. Research activities were continued, many of them in cooperation with various medical groups and with state and local health departments. Training centers in venereal disease control have been established for physicians and nurses in nine universities. The service allotted \$2,400,000 of its \$3,000,000 appropriation for 1938-1939 to state health departments, and the funds were supplemented by \$4,300,000 in state and local funds.

Government Services

Health in the Civilian Conservation Corps

The death rate in the Civilian Conservation Corps for the fiscal year ended June 30, 1939, was 2.02 per thousand as compared with 2.38 for the previous year. A great reduction in the case fatality rate in pneumonia was reported: 4.1 as compared with an average rate for the preceding five years of 12.6. The rate of incidence of pneumonia was also much lower than in any year of the corps' existence except 1934. Tuberculosis caused a slightly lower death rate in 1938, 5.3 as compared with 6 per hundred thousand the previous year. There were nine cases of typhoid with no deaths, a rate of 3.4 cases per hundred thousand enrollees. In 1935 the rate was 25.9 and the next year it dropped to 7.8, a reduction attributed to improvement in water supplies and methods of handling waste and to the greater protective value of a new vaccine introduced in 1936. The most frequent communicable diseases in the corps were influenza and other respiratory diseases.

Reorganization of Scheme for Treatment of Air Raid Casualties

When the present scheme for the treatment of casualties from air raids was prepared it was assumed that a large number might have to be dealt with quickly, and 200,000 hospital beds were made available within twenty-four hours. London had to be taken as a target area and, as far as possible, hospital patients in it were removed to safer areas. So far no air raids on any scale have occurred. There has been an opportunity to reorganize the scheme. Some 700 specialists left their private practice and work in the London hospitals for full time posts in the emergency medical service and went to staff the outlying hospitals. The salaries paid by the government involved hardship for senior men with heavy financial responsibilities. Recommendations were made by the Central Medical War Committee and accepted. The result is that only a nucleus of the medical staff will be employed full time. A large proportion of the specialist work will be done by part time officers, who will be free to engage in private practice but will undertake in consideration of the payment of \$2,500 a year to come up for service when required. They will give, without additional remuneration, whatever services the number of casualties may from time to time require of them. Thus most of the specialists will be able to return to their private work and their hospitals. The remainder of the service will be composed of another grade of part time officer, who will come up for duty when called on.

In the provinces there are many hospitals to which no whole time officer of the emergency medical service will be attached. The responsibility for treating air raid casualties will fall on the medical staff, who normally give their services free in these hospitals. Under another recommendation of the war committee which the government has accepted, they will be remunerated out of a pool provided by the payment to the hospital of 36 cents a day for each bed occupied. If the patient is treated in the outpatient department the physician will be remunerated out of a pool provided by the payment of 12 cents for each outpatient attendance. The casualties for whose treatment the government is accepting financial responsibility include not only civilians injured in air raids but also the injured taken from ships, the sick and casualties from the fighting forces and unaccompanied evacuated children.

The staffing arrangements of first aid posts have also been revised. The original arrangement provided for a medical officer and a trained nurse in attendance at each post. In the 1,150 posts in the more vulnerable areas the medical officer in charge will be paid a fee of \$375 a year, the employment to be for six months in the first instance. He will also receive \$7.50 for a session of not more than two hours and \$16 for a longer session whenever he attends at the post to deal with casualties.

Twenty-eight casualty evacuation trains have been equipped, but ten of these have been transferred to the war office for the use of the fighting services. For interhospital ambulance work 350 coaches, normally used for passenger traffic, have been converted into ambulances, but the situation is now such that 153 of them will be released.

The Army Blood Transfusion Service

With the help of the Royal College of Surgeons, the army medical service evolved an organization before the war to supply an army in the field with sufficient stored blood. When war broke out this skeleton organization was expanded to

form the army blood transfusion service, which consists of a home unit responsible for the supply of stored blood and an oversea unit responsible for its distribution. The home unit is enrolling volunteer blood donors who will give at stated intervals quantities of their blood, which is bottled and conveyed by airplane oversea. Distribution to forward units is then carried out by mobile refrigerator vans. The army blood transfusion service is responsible, either directly or indirectly, for the blood transfusion arrangements for all the fighting forces. As our military effort increases, the amount of blood required will increase. Therefore the roll of blood donors must be augmented. Within the next year the army aims at a roll of 250,000 volunteers, both men and women. They all know that the giving of blood will not impair their working efficiency, even for a short time. Blood transfusion has been performed in various recent campaigns, but no parallel exists in the world for an organization such as now exists in the British army.

Fatal Confusion of Procaine with Percaine

A physician desiring to administer a local anesthetic to a patient suffering from arthritis went to a pharmacist's shop and asked for a 2 per cent solution of procaine. He later received a bottle labeled "Not to be taken; sterile solution of percaine 2 per cent, 50 cc., Poison." He read the label and referred to the manufacturer's catalogue, where he found listed a 2 per cent solution of percaine for use "exclusively in surface anesthesia." He decided that it would serve his purpose and injected about 12 cc. around the patient's shoulder. Within five minutes she said that she felt faint. She then went into convulsions and died after about half an hour from heart failure and acute edema of the lungs.

At the inquest the physician stated that he thought that the use for surface anesthesia did not exclude subcutaneous injection. When he went to the pharmacist he did not know that there was such a preparation as 2 per cent percaine, though he had heard the name. He knew that procaine was a normal local anesthetic and that percaine was more commonly used as a spinal anesthetic and that if he had asked for percaine he would have had to sign the poison book. In cross examination he admitted that he did know that percaine was ten times as poisonous as procaine. In his evidence the dispenser of the bottle stated that the physician asked for percaine. A medical representative of the manufacturers said that percaine was a synthetic local anesthetic with properties like those of cocaine and might be injected into the tissues, but 2 per cent solution was not safe. The proper strength in this case would have been 0.1 per cent, while 2 per cent of procaine would have been suitable. A pathologist gave evidence that percaine was a proper drug to administer in this case but that the strength was too great. The coroner said that it was dangerous to give a verbal order for a drug and that when the physician found that percaine was sent he could have rung up the pharmacist. The jury returned a verdict of death from misadventure with negligence on the part of the physician and pharmacist, but not criminal negligence.

The Treatment of Tuberculosis in Wartime

In previous letters the taking over of hospitals and other institutions and adapting them to the accommodation of the large number of war casualties, military and civilian, which were expected has been reported. This of course has given rise to difficulties in the treatment of the sick. Tuberculosis is a case in point. The minister of health outlined to a deputation representing the National Association for the Prevention of Tuberculosis, the Joint Tuberculosis Council and the Tuberculosis Association the steps taken to ensure that tuberculous persons continue to receive treatment while an adequate reserve of beds is kept for air raid casualties. Although some patients had been discharged from sanatoriums and other insti-

tutions to provide accommodations for casualties, about two thirds of the 28,000 beds for the treatment of tuberculosis in England and Wales remained available for their peace time purpose. If by mistake some actively infectious persons had been discharged, they would be sought out and brought back for treatment. As more and more of the huttet annexes to hospitals were completed, so more and more beds at present allotted to casualties would be released. After an initial lull the dispensary services were returning to normal, and difficulties caused by a temporary transfer of personnel were being overcome. The importance of maintaining facilities for the surgical treatment of tuberculosis, both pulmonary and non-pulmonary, was fully recognized. The minister was also fully alive to the need for arrangements for the treatment of tuberculous patients in the army, navy and air force.

BERLIN

Curtailed Use of Boron Derivatives

The use of boron derivatives for chemical purposes has recently been curtailed. An official opinion of the state health department has been published bearing on the more economical use in medicine of these derivatives. An order prohibiting general advertising of such treatments will be soon released. Borates are more widely used as mild disinfectants and to check inflammations; according to extensive clinical experiences, very small quantities are sufficient for this purpose. In otorhinolaryngology the use of finely powdered boric acid in insufflations, as well as 2 per cent of boric acid solution, cannot be dispensed with. In pyocyanus suppuration and perichondritis, boric acid must be regarded as a superior medicament. Boron derivatives used for the eye are among the few remedies that never provoke hypersensitiveness. A boric acid ointment of 3 per cent constitutes a nonirritant, indifferent salve. (The ointment sold by druggists, according to the German pharmacopeia, contains 10 per cent.) Many surgeons and gynecologists do not like to dispense with boric acid solution for cleansing the urinary passages, while internists attach less importance to it. In obstetric practice a 3 per cent solution of boric acid is applied to the eyes of newborn infants and used for cleansing the mother's nipples after nursing. However, boiled water is said to be satisfactory. Its use varies in different gynecologic clinics, but here too substitutes for borates can perhaps be used, especially for the ointment, which is much in use. Borates have relatively little significance in internal medicine and pediatrics. Accordingly, boric acids and borates are indispensable only in relatively few therapeutic fields. Many economies can therefore be made.

Commercial Use of Mother's Milk

For years, efforts have been made to promote the availability of excess mother's milk. Regulations for the organization of collecting stations have recently been announced. Thirteen of these stations are already functioning in Germany. Large cities seem best adapted as collecting centers because of the demand as well as the possibility of securing donors for this service in connection with an existing institution, so that a daily regular supervision can be assured. Besides dealing with numerous administrative measures, the regulations deal with measures necessary to conserve the biologic value of mother's milk. Women who wish to donate their surplus milk are examined in advance for their health and the condition of nutrition. Likewise the milk itself and the health of the nurslings are regularly examined about once in four weeks. The price paid at present for mother's milk per liter (quart) amounts to from 2 to 2.50 marks (from 80 cents to a dollar). The milk when delivered at the station is at once subjected to a cooling process and examined in accordance with precise directions, bacteriologically

and chemically. If it passes the test, it is sterilized five minutes at 212 F. It is then placed at once into refrigeration and must be kept there for five hours before it can be used. Mother's milk is furnished to clinics and otherwise only on medical certification, which must state the reasons for its need. Babies after recovery of their health should not be supplied with this milk, because it is difficult of procurement. For that reason the medical prescription is valid only for two to three weeks. The selling price to private persons is at present from 5 to 6 marks (from \$2 to \$2.40) per liter.

State Commission on Cancer Control

The papers read at the scientific meeting of the state commission on cancer control were chiefly by the Austrian members of the commission. Christiani, of Vienna, discussed the relation of enzymes to cancer. He discovered that the substance in the normal serum that acts as a catalyzer on carcinomatous cells is an enzyme localized in the albuminous fraction. For this reason the assumption seems justified that the carrier of this enzyme is an albumin. Three criteria favor the enzymic nature: its thermolability, its insolubility in esters and the dependence of its effect on the hydrogen ion concentration. This substance is effective only in the hydrogen ion concentration that corresponds to the native serum. It is important that this enzyme be lacking in the carcinomatous serum. The enzymes that promote oxidation and are so necessary for the formation of a deactivation in the organism of the cancerous patient are disturbed, the ergosterol cannot undergo oxidation change and, in consequence, a deactivator is not formed. It is only through radium or roentgen irradiation that the deactivating agent can be formed in the organism of cancerous subjects. According to the speakers, direct oxidation of ergosterol by means of irradiation is involved. Three enzymes, or enzymic systems, accordingly have suffered a disturbance; the enzyme that catalyzes the carcinomatous cells, the enzymes that promote the oxidation needed to form the deactivating agent and certain dehydrases of a specific dehydrating enzymic system. This enzymic system has the function of modifying through dehydration the butyric acid that forms so that the pathologic butyric acid cholesterol ester cannot come into existence. On the question of cancer heredity Denk, of Vienna, reported that, in accordance with the data gathered by the Austrian Cancer Society, in 20 per cent of the 8,475 cases a familial connection could be proved, results which are in accord with the literature. Leb, of Graz, discussed the radiologic treatment of advanced carcinomas. In cases that seemed therapeutically hopeless, notable palliative results were achieved. Even in cases of multiple skeletal metastasis, though death could not be prevented, nevertheless in fifty-eight cases of inoperable carcinoma an improvement of the anatomic and the general condition was obtained by means of irradiation in 76 per cent. In carcinomas of the esophagus, after endo-esophageal radium and roentgen treatments the ability to swallow was improved in 62 per cent. According to Marschik, of Vienna, irradiation and surgery ought to be combined in carcinomas of the larynx. Tumors ensuing from the base of the tongue seem, he said, to cause regional metastasis sooner than those proceeding from the epiglottis. Through surgical removal of a glandular metastasis before irradiation even better results seem to be obtained. The combination of irradiation and surgery yields better and more permanent results than surgery alone. Early diagnosis is of great importance. Hofbauer, of Vienna, discussed the demarcation of surgical and radiologic indication on the basis of data of the Eiselsberg Clinic, the radiologic institute of Vienna, the radium institutes of Paris and of Stockholm and that of the literature. Carcinomas of the cheek, tongue, oral cavity, tonsils, gums and penis are to be irradiated, especially with radium; the intraperitoneal tumors are to be operated on as in the past; other types, as carcinoma of the breast, are to be operated on and subsequently irradiated. Kögl, of Utrecht, proceeding from

chemical investigations, discussed the etiology of tumors. His exceptionally careful analyses disclosed basic chemical differences between normal, benign and malignant tissues. Carcinomatous cells have lost the ability possessed by normal cells to incorporate into their structural albumin exclusively the "normal amino acids." Hueck, of Leipzig, supported by Rajewski, of Frankfurt on the Main, reported his results of pulmonary carcinomas found among the Schneeberg miners. This form of carcinoma has been legally recognized as an occupational disease. It is now assumed that the high radon content in the stone dust is the cause of this type of cancer. Mice suspended in cages in certain parts of the mines developed tumors, including malignant pulmonary tumors, quite abundantly.

STOCKHOLM

(From a Special Correspondent)

Dec. 3, 1939.

Red Cross Air Ambulance Services

Surgeon General, retired, Fritz Bauer, who has for years taken an active part in the Swedish Red Cross Society, published in a recent issue of the journal of this society an account of what it has done to promote air ambulance services since 1924, when they were first started. His is a story of pioneer work, of the expenditure of vast sums on what at times must have seemed a forlorn hope, and of disasters which have cost seven lives. The nature of air ambulance service makes this particular branch of aeronautics exceptionally dangerous; the urgent case requiring immediate operation or other treatment cannot wait till atmospheric conditions improve. In spite of often unfavorable weather, the appeals for the aid of the air ambulance service were answered in 544 of 582 cases.

Bringing his statistical information up to the end of May 1939, Surgeon General Bauer shows that, since 1924, Red Cross air ambulance services have transported 1,431 patients and have covered 402,151 kilometers. The number of patients carried may be raised to 1,543 by the inclusion of those transported by private and other airplanes. There were 218 cases of infectious disease, 480 cases of acute gastrointestinal disease, ninety-two cases of acute pneumonia, 160 cases of difficult labor or abortion and 322 accident cases transported. The fifteen cases of acute mental disease must have been the most difficult to deal with in the air. It is in the spring and autumn, when the ice is melting or beginning to form, that the difficulties are greatest in Sweden; and, when preference is shown for comparatively light machines, this is largely in deference to the thinness of the ice on which a plane may have to alight during two or three out of the twelve months in the year. Unless ice is some 20 cm. thick, a heavy airplane is apt to crash through it. The comparatively high cost of the heavier airplanes is also an important factor militating against their general use for ambulance work.

The Treatment of Dipsomaniacs

Heretofore it has been almost universally assumed that alcoholic addicts are degenerate or psychopathic individuals who are candidates for mental hospitals or special institutions. To admit such cases to a general hospital has seemed the more undesirable as they often require isolation and other special measures for which provision is made only in mental hospitals. The frequent association of alcoholism with crime has been another reason why those in charge of general hospitals have been shy of opening their doors to cases of alcoholism, acute or chronic.

The soundness of this attitude has been challenged by certain Swedish doctors, prominent among whom is Dr. J. Tillgren of the Maria Hospital, where for years the practice has been adopted of admitting cases of alcoholism on the assumption that they are just as much in need of the skilled supervision and treatment available in a general hospital as any other

case. At the Maria Hospital it is customary for acute cases of alcoholism to be discharged after about three weeks—a period so short that the patient does not miss that occupational treatment which is available in certain institutions for chronic cases.

This movement away from special homes for alcoholic addicts to general hospitals has been favored by certain shortcomings in the former. There are several such homes in Sweden with a total of about 800 beds, but in some of them there is no resident medical officer, and the visiting medical officer puts in an appearance only once or twice a month.

The Late Prof. Carl Gustaf Santesson

Professor Santesson died of coronary thrombosis July 26. His father was a Swedish professor of surgery and his mother was a sister of a Swedish professor of anatomy. Studying in Uppsala and Stockholm, Santesson in 1891 successfully defended his thesis for the degree of M.D. But at this stage in his career pharmacology enjoyed a renaissance which inspired him and made him its servant for the rest of his life. Returning from prolonged studies in Germany, Santesson taught pharmacology in Uppsala and in 1895 was appointed professor of pharmacodynamics and pharmacognosia at the Caroline Institute in Stockholm. As a research worker and as an author, Santesson was indefatigable; his publications number over 200. He was particularly interested in the action of poisons employed by primitive peoples on their arrows, and on this subject alone he published a score of studies. His modesty and kindness endeared him to many generations of medical students.

AUSTRALIA

(From Our Regular Correspondent)

Nov. 21, 1939.

Protection of Professional Incomes During Military Service

Practitioners entering military service in Australia must suffer a reduction in their income. A modern fighting force cannot function without medical services and it is necessary also to have a proportion of experienced medical officers as well as those who have recently graduated. As the majority of these men will hold the rank of captain, at approximately £400 per annum, and experience indicates that the income of a practice rapidly diminishes in the absence of the principal, these men will be called on to make a sacrifice out of all proportion to that imposed on those who do not join the services. The council of the Victorian branch of the British Medical Association, therefore, has devised a scheme for the protection of professional incomes during military service. It provides for the establishment of an income insurance fund by means of which losses may be spread more evenly on the whole of the profession. Men who remain in civil and departmental practice and practitioners on military duty who suffer no loss of income are invited to contribute to this fund, which will be applied to rendering financial assistance to men on active service who do suffer loss of income. The proposed contributions have been equitably arranged on a percentage basis of gross professional income earned, graduated to spread the burden in accordance with ability to pay. These contributions might be regarded as premiums for insurance against a risk—loss of professional income—which it is impossible for any practitioner at this stage to know that he will not himself be called on to suffer. Membership in the fund is voluntary. Financial assistance for a member shall not exceed £500 per annum, and in no case will it be greater than an amount, with the member's military pay, to provide him with an income of more than £900 per annum.

A second part of the scheme provides for the organization of groups of members of the profession for the purpose of carrying on the practices of members of the group who may

be called up for military duty. The experience of the last war has not been forgotten, when, all too commonly, those who kept the home fires burning took the opportunity to warm themselves by the fire. This second portion of the scheme provides also that no practitioner shall commence practice in a group area without purchase for the duration of the war and six months after, that all practitioners refuse to attend for at least twelve months the patients of another practitioner who has resumed practice after military service, that all appointments held on behalf of the absentee be returned and that all appointments made during the war be only temporary and be thrown open for application at the termination of the war.

By offering their full support of these recommendations, members of the British Medical Association in Victoria will fulfil one of its first objects: "the maintenance of the honor and interests of the profession."

The Walter and Eliza Hall Institute of Research

A great deal of the original research which is making Australian workers known overseas has come from the Walter and Eliza Hall Institute of Research in Pathology and Medicine, which has published its twentieth annual report. The trustees of the late Walter and Eliza Hall completed the pathologic block of the Royal Melbourne Hospital and provided a sum of £2,500 annually toward the upkeep of the institute. Since 1930 this sum has been £3,200 a year. The work of the institute is undertaken under conditions which are at once an advantage and a disadvantage. The routine services of the Royal Melbourne Hospital in bacteriology and pathology are carried out at the institute, and work of this kind must be a distraction to the director and certain of his co-workers, but it does bring the hospital, as it were, into the institute, and this close association cannot fail to be a stimulus to the members of the honorary staff. Pride of place is given in the report to the work of Dr. F. M. Burnet and other members of the virus department. This department has been financed by annual grants of £1,000 from the Rockefeller Foundation and of the same amount from the commonwealth department of health. Among the conditions investigated during the past twelve months have been poliomyelitis, herpes, influenza, Q fever, psittacosis and myxomatosis. In the department of physiology work has been done by Dr. W. Feldberg, Dr. E. R. Tretliewie and the director (Dr. C. H. Kellaway) on tissue injury by snake venom, staphylococcus toxin, mercury bichloride, radiant energy, anesthetics and anaphylaxis. In all, thirty important papers have been published, and it need hardly be stated that the published papers do not represent all the work that has been proceeding at the institute. The financial statement shows that this work has all been carried out for the modest sum of £5,399.

Marriages

ANGUS MORRIS McDONALD JR., Charlotte, N. C., to Miss Mary Letty Mebane, of Greensboro, in October.

JOHN AUSTIN RYAN, Milan, Mich., to Miss Alma Lloyd Ranson, at Durham, N. C., November 4.

J. THOMAS MILLINGTON JR., Wilkes-Barre, Pa., to Roberta Walton, of Kingston, October 15.

JOHN N. McCANN to Miss Mary Louise Radowick, both of Youngstown, Ohio, October 16.

PAUL RUSSELL GRIFFITH to Miss Ida Louise McCoy, both of Berwyn, Ill., November 4.

SAMUEL KENNETH GERSON, Cleveland, to Miss Jean Long, at Canton, Ohio, October 25.

VINCENT J. GAUL, Chicago, to Miss Ruth Wigent, of Fort Wayne, Ind., in October.

Deaths

Amédée Granger ☉ New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1901; professor of radiology, Louisiana State University Medical Center; professor of radiology at the Tulane University Graduate School of Medicine, 1916-1931; chief of service of radiology, Charity Hospital, 1905-1921, and director of the department since 1921; veteran of the Spanish-American War; member and vice president in 1929 of the Radiological Society of North America; member of the American College of Radiology and chancellor, 1923-1926; member of the French-Speaking Doctors of North America and in 1934 vice president; past president of the Louisiana State Society of Radiology and the Orleans Parish Medical Society; member of the American Roentgen Ray Society; was decorated by the French, Belgian and Italian governments for his work on x-ray; in 1926 was awarded the gold medal of the Radiological Society of North America; author of "Radiologic Atlas of the Pathological Changes of Bones and Joints" published in 1911; aged 60; died, December 15.

William H. Washburn, Milwaukee; Rush Medical College, Chicago, 1877; member of the State Medical Society of Wisconsin; secretary of the Section on Practice of Medicine of the American Medical Association in 1894; past president of the Medical Society of Milwaukee County and the Milwaukee Academy of Medicine; professor of medicine emeritus at Marquette University School of Medicine; served at various times and in various capacities on the staffs of the Johnston Emergency Hospital, St. Joseph's Hospital, County Hospital and Milwaukee General Hospital; member of the medical advisory board during the World War; aged 85; died, October 4, of myocarditis.

Thomas John Scanlan ☉ Boston; Tufts College Medical School, Boston, 1903; member of the New England Obstetrical and Gynecological Society; served during the World War; chairman of the board of trustees of the Boston State Hospital; served in various capacities and at various times on the staffs of the Foxboro (Mass.) State Hospital, Boston Dispensary, Deer Island Hospital, St. Elizabeth's Hospital and the Winthrop (Mass.) Community Hospital; aged 67; died, October 18, at his home in West Roxbury.

Joseph Lee Kirby-Smith ☉ Jacksonville, Fla.; University of the South Medical Department, Sewanee, Tenn., 1906; first lieutenant and acting assistant surgeon in the U. S. Public Health Service during the World War; on the staffs of St. Luke's Hospital, St. Vincent's Hospital and Duval County Hospital, Jacksonville, and the Flagler Hospital, St. Augustine; past president of the Florida Society of Dermatology and Syphilology; aged 57; died, November 5.

George Edward Decker ☉ Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; fellow of the American College of Surgeons; at one time president and medical director of the Register Life Insurance Company; at one time member of the state boards of health and medical examiners; formerly member of the school board; formerly on the staff of St. Luke's Hospital; aged 66; died, November 3, in the Holmes Hospital, Cincinnati.

Edward M. D. Libby ☉ Iron River, Mich.; Rush Medical College, Chicago, 1898; fellow of the American College of Surgeons; past president of the Upper Peninsula Medical Society and the Dickinson-Iron Counties Medical Society; member of the school board for many years; aged 62; died, November 10, in the Iron Mountain (Mich.) General Hospital of injuries received in an automobile accident.

Louis Schneider Weaver ☉ York, Pa.; Johns Hopkins University School of Medicine, Baltimore, 1904; member of the American Roentgen Ray Society; fellow of the American College of Surgeons; veteran of the Spanish-American and World wars; trustee of the Gettysburg (Pa.) College; surgeon to the York Hospital; aged 62; died, October 1.

William Richardson Culbertson, Coeburn, Va.; Baltimore University School of Medicine, 1904; served during the World War; formerly health officer of Wise County; part owner of the Coeburn Hospital; aged 60; died, November 6, at the New Altamont Hospital, Christiansburg, of pneumonia as the result of injuries received in an automobile accident.

Frances Culbreth Van Gasken, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1890; member of the Medical Society of the State of Pennsylvania; formerly

professor of clinical medicine at her alma mater; on the consulting staff of the Woman's Hospital; aged 79; died, October 24, at Drexel Hill.

Roscoe Addison Mitchell, Marshall, Ill.; State College of Physicians and Surgeons, Indianapolis, 1907; member of the Illinois State Medical Society; for many years bank president; served during the World War; aged 60; died, November 12, at the Paris (Ill.) Hospital as the result of a cerebral hemorrhage.

Corbett Edward Tumlin * Miami, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1915; member and past president of the state board of medical examiners; on the staffs of the Jackson Memorial Hospital, Riverside Hospital and Victoria Hospital; aged 46; died, November 6.

Joseph Peter Weyrens, Scottsbluff, Neb.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1907; member of the Nebraska State Medical Association; formerly county physician and chairman of the county medical advisory board; aged 62; died, October 7, of leukemia.

William Boswell Small, Waterloo, Iowa; Chicago Medical College, 1890; member and past president of the Iowa State Medical Society; fellow of the American College of Surgeons; member of the House of Delegates of the American Medical Association 1917-1920; aged 77; died, October 9.

Charles Edward O'Connor, Kingston, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1898; associate professor of ophthalmology and otolaryngology at his alma mater; on the staff of the Hotel Dieu Hospital; aged 65; died, November 7, in St. Michael's Hospital.

Clarence Eugene De Groot, Muskogee, Okla.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1904; member of the Oklahoma State Medical Association; past president of the Muskogee County Medical Society; federal jail physician; aged 60; died, October 26.

Nicholas Thomas Grace, Brooklyn; Long Island College Hospital, Brooklyn, 1931; member of the Medical Society of the State of New York; on the staffs of St. Mary's Hospital, Brooklyn Hospital and the Long Island College Hospital; aged 33; died, November 9.

Ernest M. Haggard, Indianapolis; Physio-Medical College of Indiana, Indianapolis, 1894; on the consulting staff of the City Hospital; on the visiting staff of the Methodist, St. Francis and St. Vincent's hospitals; aged 77; died, November 7, of cerebral hemorrhage.

Lewis Nostrand Anderson, Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the Medical Society of the State of New York; on the staff of St. John's Hospital; aged 67; died, November 10.

Clarence Dale Fulkerson, French Lick, Ind.; Medical College of Indiana, Indianapolis, 1898; member of the Indiana State Medical Association; served during the World War; aged 68; died, November 4, in the Veterans Administration Facility, Hines, Ill.

Richard H. Simpson, Dallas, Texas; Arkansas Industrial University Medical Department, Little Rock, 1887; Kentucky School of Medicine, Louisville, 1899; member of the State Medical Association of Texas; aged 77; died, October 29, of chronic nephritis.

Burt Edward Scott, Berlin, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1901; member of the State Medical Society of Wisconsin; served during the World War; on the staff of the Berlin Memorial Hospital; aged 67; died, October 2.

Charles Rohrer Kiser * Madison, Ill.; Medical College of Ohio, Cincinnati, 1895; past president of the Madison County Medical Society; aged 72; died, November 5, in a hospital at Hamilton, Ont., of a skull fracture received in an automobile accident.

Theodore Miller * Cleveland; Harvard Medical School, Boston, 1908; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; on the staff of St. Luke's Hospital; aged 55; died, November 7.

David Leonard Hedberg, Evanston, Ill.; Northwestern University Medical School, Chicago, 1909; served during the World War; at one time police surgeon; aged 61; died, November 19, in the Veterans Administration Facility, Dearborn.

Wiley S. May, Little Rock, Ark.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1893; College of Physicians and Surgeons, Little Rock, 1908; Kansas City (Mo.) College of Medicine and Surgery, 1920; aged 68; died, November 3.

Christopher C. Threlkel, Morgantown, Ky.; University of Tennessee Medical Department, Nashville, 1898; member of the Kentucky State Medical Association; for many years county health officer; aged 66; died, November 9.

Francis Owington Rogers, Little Rock, Ark.; University of Maryland School of Medicine, Baltimore, 1901; member of the Arkansas Medical Society; aged 63; died, November 8, in the Lynnhurst Sanitarium, Oakville, Tenn.

Herbert Elmer Stevenson, El Paso, Texas; Rush Medical College, Chicago, 1899; member of the State Medical Association of Texas; veteran of the Spanish-American and World wars; aged 68; died, November 2.

Joseph James McNamara, Rochester, N. Y.; Fordham University School of Medicine, New York, 1917; member of the Medical Society of the State of New York; aged 47; hanged himself, October 1.

Irving Joseph Weiss, Callender, Iowa; Creighton University School of Medicine, Omaha, 1931; member of the Iowa State Medical Society; aged 33; died, October 17, of acute myelogenous leukemia.

David M. Brower, Ashland, Ore.; Willamette University Medical Department, Salem, 1888; past president of the Jackson County Medical Society; aged 81; died, October 27, of cerebral hemorrhage.

Homer Chambliss, Cairo, Ill.; Meharry Medical College, Nashville, Tenn., 1924; member of the Illinois State Medical Society; aged 40; died, November 8, in the Passavant Hospital, Chicago.

Clinton Hill Morgan, Knoxville, Tenn.; University of Tennessee Medical Department, Nashville, 1899; member of the Tennessee State Medical Association; aged 64; died, November 11.

Frederick William Winter, Adams, Neb.; State University of Iowa College of Homeopathic Medicine, Iowa City, 1880; aged 87; died, November 12, in Lincoln of prostatic hypertrophy.

Roy Ulysses Stevens * Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, Kan., 1921; aged 48; died, October 30, in Excelsior Springs of carbon monoxide poisoning.

George W. Lamb, Philadelphia; University of the South Medical Department, Sewanee, Tenn., 1898; also a clergyman; aged 64; died, October 30, at the Episcopal Hospital of heart disease.

Edgar M. Harris, New Haven, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; at one time health officer; aged 64; died, November 7, of diabetes mellitus.

Sarah Shomer, Miami, Fla.; University of Michigan Medical School, Ann Arbor, 1931; aged 43; died, October 7, in the St. Francis Hospital, Miami Beach, of septicemia.

Oliver James Roskoten * Peoria, Ill.; Rush Medical College, Chicago, 1882; an Affiliate Fellow of the American Medical Association; aged 81; died, November 5.

Earl E. Efner, Oroville, Wash.; Sioux City (Iowa) College of Medicine, 1901; member of the Washington State Medical Association; aged 64; died, October 6.

Thomas W. Taylor, West Point, Ga.; University of Georgia Medical Department, Augusta, 1892; aged 74; died, November 1, in the City-County Hospital, La Grange.

Andrew Tennyson Custer, Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; served during the World War; aged 66; died, November 11.

John Nicoll Dimon, New London, Conn.; Long Island College Hospital, Brooklyn, 1883; aged 77; died, October 10, of chronic myocarditis and arteriosclerosis.

Charles T. Walton, Port Henry, N. Y.; Albany Medical College, 1886; aged 80; died, October 31, of influenza, hypostatic pneumonia and multiple arthritis.

Frank Shapiro, New York; Long Island College Hospital, Brooklyn, 1915; member of the Medical Society of the State of New York; aged 52; died, October 27.

George Leslie Lyne, Medina, Ohio; Dartmouth Medical School, Hanover, N. H., 1896; aged 71; died, November 10, of arteriosclerosis.

Ulric Antonio Bedard, Kankakee, Ill.; Rush Medical College, Chicago, 1894; aged 73; died, November 11, of coronary thrombosis.

Bureau of Investigation

A "DIABETES CURE" FRAUD

"Dia-San" Concern Debarred from the Mails

A "diabetes cure" put out under a number of names and claimed to be "a formula of herbs used in Germany's great hospitals" has been debarred from the mails by the issuance of a fraud order against the Dia-San Laboratories, Inc., Dia-San Corporation and Albert Hofmann, president, of Fort Wayne, Ind.

The "cure" was sold under such designations as "Hofmann's Medicinal Natural Herb Tea," "Dia-San," "Dia-San Diuretic R 212," "Dia-San Herb Tea 212" and "Original Old Country Dia-San R 212." The Post Office Department reported that the business was started in 1930 and that though the concern's titles and literature indicated that it was incorporated, Hofmann informed that department that it was not, and that he was the sole owner of the enterprise.

Many of those who inquired of Hofmann about the treatment received a form letter reading in part:

A few years ago some nationally known chemists of Germany prepared a combination of herbs found in that country and in Eastern Europe for the treatment of Kidney and Bladder troubles. This preparation grew into such favor that most of the great health centers of Europe are now using it.

The formula has been obtained and the herbs are imported at present and the preparation is now available in the form of DIA-SAN DIURETIC R 212. This was formerly called Original Old Country Herb Tea R 212.

DIA-SAN contains beneficial Herbs, the extract of which is in constant use by physicians and hospitals. This particular combination of herbs, blended to soothe irritated mucous membranes, gives us a formula that may be used with great benefit in DIABETES, RHEUMATISM, BRIGHT'S DISEASE . . . Kidney and Bladder disorder, Backache, Headache, Leg Pains—Swelling, Dizziness or Defective Vision, yield quickly to the DIA-SAN Treatment. . . . We make no false claims for DIA-SAN. It will do just what we say it will. We desire to help you and convince you that famous DIA-SAN is a wonderful remedy. . . .

And finally, in a booklet:

Like harmony in music, so, blended is the flavor in our remedy. DIA-SAN contains medicinal power as well, and is very beneficial to the user. It is a New Discovery in the art of preparing, blending and combining herbs for taste as well as usefulness. . . . The Herbs are imported from Germany and carefully compounded to make a palatable diuretic.

The booklet represents that the product is good not only for "diseases of the urinary organs" but also for "diseases of the prostate," "dropsical and renal disease," "gonorrhea" and "heart diseases." Of course there are the usual testimonials.

Microscopic analysis of the stuff by government chemists is said to have shown that it consisted of the leaves of buchu, bearberry and mint, stems of horsetail herb, anise seed, licorice root, beans, corn silk, wintergreen, and traces of other herbs not named.

Hon. Vincent M. Miles, Solicitor for the Post Office Department, in his memorandum recommending that the Postmaster General debar the thing from the mails as a fraud, cited medical evidence that, while the mixture when used as directed would be slightly laxative and by irritating the kidneys might slightly increase the flow of urine, such increase would have no valuable effect in removing the various poisons from the blood stream; that it would have no beneficial action on diabetes and that gout, rheumatism, neuritis and prostatitis arise from various causes such as venereal diseases and foci of infections, all of which would be affected by this nostrum; and that there is no known drug or combination of drugs that will be effective in all cases of high blood pressure, kidney and bladder troubles, disorders of the prostate gland, dropsical and renal diseases, gonorrhea, and heart trouble. Nevertheless the Dia-San treatment was represented to cure or benefit all such conditions and to enable the victims of them to regain and retain "lasting" good health.

The memorandum also brought out that Mr. Hofmann was born in Germany forty-five years ago, came to America in 1923 and took out first papers for citizenship but never proceeded further; that in addition to his nostrum business he works as

a knitter in a knitting plant in Fort Wayne, and that neither he nor any one else connected with his nostrum business possesses any medical knowledge. In addition, Judge Miles's memorandum referred to a case in which *Alfred Hofmann*, trading as the Original Old Country Remedy Co., was prosecuted in 1934 under the Food and Drugs Act for selling his "Old Country Dia-San" in interstate commerce under fraudulent claims. The defendant (presumably the *Albert Hofmann* mentioned in the fraud order) pleaded guilty but, also pleading poverty, was fined the ridiculously small sum of 5 cents!

In the Post Office investigation Hofmann claimed that the cited misrepresentations for his product had been discontinued a long time ago, but the government presented evidence that even "within recent months" Hofmann had sent out literature soliciting the purchase through the mails of the treatment for the diseases mentioned. Accordingly, a fraud order was issued on May 8, 1939, covering the names Dia-San Laboratories, Dia-San Laboratories, Inc., Dia-San Corporation, Albert A. Hofmann and Albert Hofmann, President.

A "GOITER CURE" FRAUD FROM MONTREAL

Lemmert Nostrum Debarred from United States Mails

A Canadian "goiter cure" advertised in periodicals in this country has been barred from the United States Mails by the issuance of a fraud order against a Mrs. Emma Lemert (or Lemmert) of Montreal.

The memorandum on the case issued by Hon. Vincent M. Miles, Solicitor for the Post Office Department, quoted a typical advertisement:

GOITRE
"External Treatment. Will bring prompt relief. Many testimonials Free Booklet.

EMMA LEMMERT REG. Box 734, Montreal, Canada."

Many of those who answered it received a printed letter reading:

Dear Sir or Madam:

We take pleasure in sending you our booklet concerning goitre. Read it carefully, it will interest you. You will find in it copies of a few certificates from persons who have been cured with our treatment.

This goitre cure will not only remove the tumor, but all symptoms which affect goitre sufferers will also disappear. It will be impossible for anyone to detect that you ever suffered with goitre.

We hope that you will be convinced that our treatment can do for you what it has done for so many others, and that we will soon be able to put your name on our list of patients whom we have cured.

When ordering, please fill the questionnaire enclosed herein.

The booklet mentioned was a small six-page leaflet in which Mrs. Emma Lemert used a supplementary title, "Mde. Marie Girardin," and claimed "Over 25 years of success" with "this wonderful goitre cure," which she also described as "an external treatment so everyone may use it, without any fear of bad effects . . . it has cured the worst cases . . . quite different of all the other treatments . . . since 1914, when this treatment was offered to the public, hundreds of people of all parts of America were cured with that remedy . . . Mrs. Lemert's Treatment will not only remove the tumor, but all symptoms which affect goitre sufferers will also disappear (such as Protruding Eyes, Heart's Palpitations, Nervosity, Etc.) after using this wonderful treatment."

There were testimonials, alleged to have come from persons claiming to have used the preparation and to have been completely cured of various types of goiter.

The treatment was sent out in small metal boxes, each full box containing about one ounce, to be used daily. Users were directed to apply it at bedtime after washing the throat with lukewarm water, then massage the throat and finally apply the ointment, which, covered with cotton, was to be left on over night, and part of the next day if possible.

Chemical analysis of the ointment was reported to reveal that it consisted of a sulfonated bitumen (ichthammol) in a lanolin base. Iodine or alkaloids were not detected.

Judge Miles's memorandum cited the medical evidence in the case as showing that in some simple colloidal goiters iodine may be helpful, whereas iodine was not found in the Lemert "cure." The evidence further showed that large adult goiters or other tumors of the thyroid gland, regardless of type, are never removed by external application of medicines or, in fact, by any other means than surgery, radium or the roentgen ray. The memorandum pointed out that many tumors at the side of the neck may be malignant and frequently cancerous and that the delay caused by the use of Mrs. Lemert's nostrum might prevent the patient from obtaining proper treatment and even result in death.

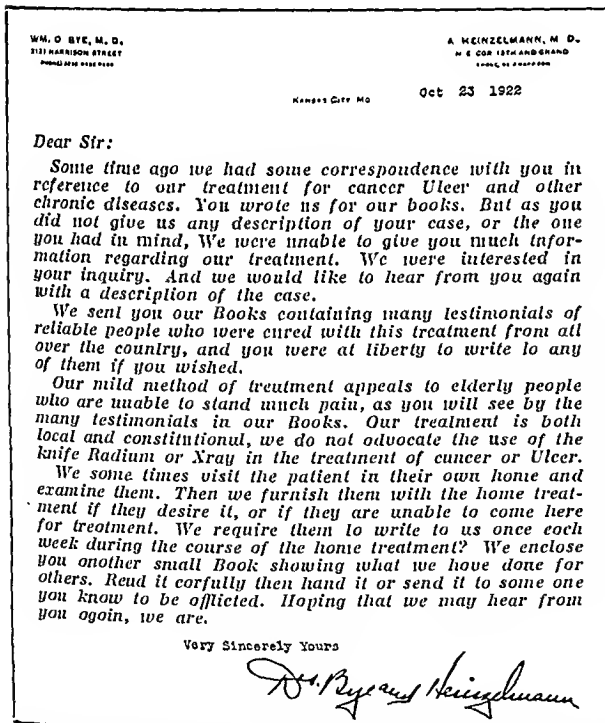

On April 3, 1939, the United States mails were closed to this Canadian fraud.

A "SYPHILIS CURE" FRAUD

Heinzelmann Company of Kansas City Is Banned from Mails

The sordid story of a "cancer specialist" who also promoted a "syphilis cure" is revealed in a fraud order by which the Post Office Department has debarred the Heinzelmann Company, of Kansas City, Mo., from the use of the mails.

This enterprise was started in 1924 by an Arthur Heinzelmann, who obtained a medical degree in 1907 from the Eclectic Medical University, of Kansas City, a low-grade school long since closed. Previously Heinzelmann's name had appeared as "superintendent" on the letterhead of the Cliff View Sanatorium of Kansas City, a "cancer cure" institution. Later he joined a William O. Bye of unsavory repute in another Kansas City cancer cure scheme. This combination and the nature of the business are best illustrated by the following letter sent in 1922 to an inquirer, who forwarded it to the Bureau of Investigation:

Reproduction of letterhead and signature (reduced); body of letter reset in type.

Further details of the Heinzelmann-Bye business appeared in a report which the Bureau of Investigation published in *THE JOURNAL*, June 3, 1933.

Not content with limiting his nefarious activities to the cancer cure field, this individual started his syphilis cure fraud in 1924. The latter enterprise was called the Heinzelmann Company and sold through the mails a nostrum called "Dr. Heinzelmann's Remedy."

The first government agency to concern itself with this scheme was the Federal Trade Commission. On Dec. 26, 1937, the Commission announced that it had got Frances M. Heinzelmann and Etta Campbell, trading as the Heinzelmann Company, Kansas City, to sign a stipulation promising to cease representing that "Dr. Heinzelmann's Remedy," also known as "Blood Disease Formula," can be used by the sufferer at home with beneficial results regardless of the cause of the ailment or the length of time it has existed. *The defendants were reported as admitting that there is no blood disease for which their product could be considered a satisfactory remedy.*

Two years later, in the memorandum of Hon. W. E. Kelly, Acting Solicitor for the Post Office Department, recommending that the United States Postmaster issue a fraud order against the business, it is reported that after Heinzelmann died in April 1936 the scheme was continued by his widow, Mrs. Frances M. Heinzelmann, with the aid of a physician, not named, until September 1936, when Mrs. Etta Campbell became a silent partner.

The memorandum states further that after an investigation of the enterprise by a Post Office inspector the concern was called on to show cause why a fraud order should not be issued against it for selling its product through the mails under the false and fraudulent representations that it would "free" victims of syphilis, of that "terrible disease" and prevent locomotor ataxia, organic heart disease, paresis, blindness, the birth of syphilitic children and other afflictions and conditions incident thereto. No fraud order was issued at that time, however, because certain statements made by Mrs. Heinzelmann and other evidence indicated that the preparation was not being sold through the mails for the treatment of syphilis.

These statements and "other evidence," however, must have been spurious or at least misleading, for it was found later that letters urging the purchase of additional medicine were addressed by the promoters of the scheme to customers who had previously purchased the remedy as a syphilis cure. The later evidence showed, in fact, that the promoters were "continuing" to offer to sell the cure through the mails as a treatment for "bad blood" resulting from syphilis, anemia, malaria, pellagra, gonorrhea, tuberculosis and some other conditions. All this in spite of the fact that two years previously Mrs. Heinzelmann had admitted to the Federal Trade Commission that the product was good for nothing.

Analysis by government chemists was said to show that the Heinzelmann nostrum was composed of sodium iodide, alcohol, sugar and plant extractives, including bitter principles, tannins and saponins. Expert medical evidence was produced to show that the term "bad blood" is frequently used by laymen to describe a condition resulting from any number of diseases, including syphilis, pellagra, gonorrhea, tuberculosis and anemia, but that "purifying" such "bad blood" requires treatment of the cause thereof, a procedure which necessitates careful diagnoses based on examination of the patient in person and in some cases on laboratory tests. Moreover, it was pointed out that, on arriving at a diagnosis, the physician must adapt his treatment not only to the special disease found to be present but also to the stage to which it has progressed and to the patient's individual needs.

The medical evidence further showed that, despite use of the Heinzelmann treatment by persons afflicted with syphilis, the blood and spinal fluid tests would remain positive and the condition would progress, with paresis and locomotor ataxia as possible after-effects. Also the evidence showed that the Heinzelmann treatment was not in itself a competent treatment for the other conditions in which it was supposed to "purify" "bad blood." Mrs. Heinzelmann denied that her "remedy" was sold for these conditions mentioned and claimed that it was promoted only for its "tonic properties"; and, further, that the business was "decreasing rapidly." These statements were contradicted by evidence which, Judge Kelly declared, showed that the business was a scheme for obtaining money through the mails under false and fraudulent pretenses and promises. Accordingly a fraud order was issued against it on April 1, 1939.

Correspondence

GLAUCOMA: A MEDICAL PROBLEM

To the Editor:—In civilized countries glaucoma takes first place among the causes of blindness. De Grosz says that more blindness results from this disease than from syphilis, tuberculosis, gonorrhea or even injuries. Yet there is no subject affecting the eyes which is less understood or for the prevention of which less is being done. The communication in THE JOURNAL Nov. 26, 1938, asking whether the views of Magitot on the origin of glaucoma were generally accepted was important.

Magitot is one of the most eminent French ophthalmologists. He was one of four reporters on glaucoma at the thirteenth Ophthalmologic Congress, the Netherlands, 1929, and the summary of the views he expressed was embodied in papers through four succeeding numbers of the *Annales d'oculistique*. These views were not generally accepted by the medical profession. One reason why they are not more widely accepted is that they are not generally understood. Magitot, writing in French, is not accessible to the majority of English readers. While he has been the guest of great medical societies in this country, his writings usually appear in French periodicals. These are not commonly read by American physicians, and abstracts are inadequate to give their full import. Beard's translation was a valuable addition to our knowledge of this subject.

The accepted view by ophthalmologists is that glaucoma is a disease characterized by increased tension of the eyeball, that this is produced by a narrowing or closure of the pathways of exit of the fluids from the anterior part of the eye and that, failing reduction of this tension by the use of myotics and more especially pilocarpine, an operative procedure relieving this tension is the only means of relief.

Magitot and a growing number of writers are accepting the view that the closure of the anterior pathways is due to an increase in the amount of the intra-ocular fluids and is a consequence rather than a cause of the disastrous series of events which follow.

A theory is only of academic value unless it has a practical application. Acceptance of the view that the obstruction is mechanical and can be relieved only by mechanical measures not only shuts off the consideration of other means of relief but also closes the mind to the acceptance of possible causative conditions which might be governable.

The importance of an understanding of this matter far transcends the acceptance or the rejection of a theory. Some of these points Magitot has elaborated in the first number of the *Acta ophthalmologica* of the current year in a paper of some seventy pages. Whether this view is correct or not, it opens a wide field for further research and the adoption of other clinical measures before the period has arrived in which operative measures become imperative. The prodromal symptoms often extend through a period of years and it is their early recognition which is important. When accommodation becomes uncertain, when it is difficult to see after dark, when there are occasional phosphenes before the eyes and temporary clouding, all these may indicate transitory intra-ocular pressure. These are known to be increased by emotions, by excesses, by physical disturbances, by focal infections and by other controllable causes. These and other symptoms are frequently overlooked even in our best clinics, and are not adequately emphasized in most of our textbooks, during a time in which relief is possible. It is during this period that treatment can be most effectively applied, and it is then that it is most commonly overlooked. It is unquestionably necessary that every glaucomatous eye should be subject to constant supervision by one adequately trained to measure the tension, to take visual fields and to study eyegrounds. But

this should be carried out in closest cooperation with the internist, who takes into account such general physical changes as may be found to be present.

As Edward Jackson has well put it, "The common belief that glaucoma means either operation or blindness is not correct. We must admit there is something besides operation that can cure glaucoma. To determine what this something is, is a proper subject for investigation and experiment." But the unnecessary eye mortality due to glaucoma will not be limited until the public and the medical profession at large are taught to recognize the early symptoms of the oncoming of glaucoma before pathologic changes occur and while there is still a possibility of saving the sight.

PARK LEWIS, M.D., Buffalo.

THE HIPPOCRATIC OATH

To the Editor:—I was surprised to read the editorial "A New Interpretation of a Paragraph in the Hippocratic Oath" in THE JOURNAL November 4. The "new interpretation" is meaningless and not in accord with the spirit of the rest of the oath. It vitiates one of the most important paragraphs in the entire oath.

The scholar who suggests this interpretation is more of an etymologist, lexicographer and perhaps syntaxologist than a philologist. Yet I suspect that he will receive a vote of appreciation from practitioners who are "cutting persons suffering from a stone" instead of "leaving it to practitioners of that art," because this "interpretation" would put a final quietus on their conscience for doing so.

It is a well recognized fact that words denote, connote and have a figurative meaning. Sometimes a word is used for one of these reasons, sometimes for another, and taken in the context may have very different meanings. "Cut up" in a salad recipe means to reduce to fine particles. "Cut up" also means capricious behavior. The word "cut" is often used to signify a surgical operation, and in the Cow County, from the Rio Grande to Canada, the word "cut," when referring to an animal, means to castrate. One who carries out a surgical procedure is known as an operator. The proprietor of a pool hall is called an operator. An agent of the Federal Bureau of Investigation is called an operator. Some post-meta-scholar, two thousand years from now, might say that in the United States of today the secret police performed surgical procedures and were proprietors of pool halls.

In "interpreting" a word when several alternatives are possible, one must be guided by the spirit and general meaning of the entire manuscript. This is a well recognized principle in law. Applying this to the paragraph in question, one must first get the spirit of the "oath." "I will teach medicine to those who are properly qualified and to none others." "I will use that treatment which is for the benefit of the patient . . . and refrain from voluntary acts of mischief and corruption." "I will not give a woman an instrument with which to produce an abortion." In no place does it say I will not associate with unqualified students, quacks, charlatans and abortionists, all of which I will not do, but "with purity and holiness I will live and practice my art."

In this paragraph in the oath, granted that the word in question means to castrate and that only, if Hippocrates did not approve of castration while operating for a stone this part of the paragraph would mean "I will not castrate a person while removing a stone." But if this is considered in connection with the latter part of the sentence "but will leave it to practitioners of that art," it is clear that Hippocrates must have used the word in a figurative sense or, since and if such mutilation was a common practice, he used it because it was common but as an example to make plain an important and thoroughly hippocratic ethical principle: if I am to treat for the benefit of the patient, abstain from voluntary acts of mischief, live and prac-

tice in purity and holiness, honored by all men. That principle is "I will not attempt procedures which I am not qualified to perform but will leave them to those who are qualified." If medical men today would make that paragraph a part of their daily work, they as individuals and the medical profession as a whole would be more honored by all men, and some patients would not be hurried to their graves because medical men did not leave to practitioners procedures which they themselves were not qualified to carry out.

All the scholars who have translated the oath from the time of Hippocrates have not been mistaken. I hope that the "new interpretation" never finds its way into the official printed oath.

Professor of Pathology and Lecturer
on History of Medicine, University
of Oklahoma School of Medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LEAD AND ARSENIC IN TOBACCO

To the Editor:—In the annual cumulative issue of *Consumer's Research Bulletin* for Sept. 4, 1939, the statement was made that the lead content of five brands of cigaret was found to vary from 11 to 30 parts per million and that the arsenic content varied from 6 to 14 parts per million. The brands tested were Camels, Lucky Strikes, Pall Mall, Murad and Lord Salisbury. Are these ranges of values for arsenic and lead too high for safety for one who smokes one packet of cigarets daily? Are these values correct ones and if not what are correct values?

M.D., Pennsylvania.

ANSWER.—In a recent article two Canadian investigators (Zeidler, F. A. J., and Wagner, W. J.: The Lead and Arsenic Content of Canadian Domestic Tobaccos, *Canad. Pub. Health J.* 28:582 [Dec.] 1937) reported an average of 22 parts per million of lead to the package of domestic cigarets. Nine analyses of oriental tobaccos showed an average lead content of 2.5 parts per million to a package. The arsenic content of these tobaccos was not determined but the authors estimate that it may amount to about one half of the lead content, or 11 parts per million per package of domestic tobaccos. These amounts of lead and arsenic in tobacco are attributed chiefly to the lead arsenate used as an insecticide for the horn worm, the wire worm and the flea beetle. Some tobacco leaves contain 100 times the lead tolerance placed by the United States government on foods. This varies from year to year and place to place depending on the requirements for insecticide. Although tobacco is an agricultural product, the restrictions placed on foods have not been applied to tobacco with comparatively high contents of lead and arsenic.

Lead and arsenic may enter the system during smoking by inhalation and by ingestion secondary to solution in the saliva and mucus. It has recently been shown that saliva dissolves five times as much lead arsenate as blood serum. The actual amount of lead and arsenic dissolved in saliva and swallowed during smoking is not known.

Some investigators have reported on the amounts of lead and arsenic volatilized from tobacco during smoking. Gross and Nelson (Arsenic in Tobacco Smoke, *Am. J. Pub. Health* 24:36 [Jan.] 1934) found that the average arsenic content of unnamed American brands was 114 parts per million to the package. A little more than one third of the arsenic was volatilized during smoking but only 10 per cent was found in the puffed smoke. A considerable portion of the arsenic remains in the unburned tobacco, is volatilized in the unpuffed smoke and is absorbed by the tobacco in the butt. It has been computed that one fifteenth of the total lead present in cigarets is found in the puffed smoke.

How much lead and arsenic constitutes a daily toxic dose is a controversial question. It is a complicated problem. The safe limit of lead in air breathed has been set by the United States Public Health Service and the National Safety Council as between 150 and 600 micrograms per cubic meter of air. The oral daily toxic dose of lead as given in the literature varies from 100 to 1,000 micrograms. The lead tolerance placed on

foods by the United States government is about 2.5 parts per million and the arsenic tolerance is 1.06 parts per million, both expressed as the elements. If one fifteenth of the lead and arsenic is inhaled in the smoke of one cigaret and the tobacco contains 22 parts per million of lead and 11 parts per million of arsenic, and an average package of cigarets contains 21 Gm. of such tobacco, the lead inhaled as an oxide will amount to 70 micrograms and the arsenic roughly to 35 micrograms. This value for lead is approximately one half of the lower limit established by the United States Public Health Service for lead in air. These approximate calculations may indicate the desirability of further study of the lead content of the air in rooms filled with tobacco smoke. How much lead or arsenic is actually taken into the body, retained and excreted on exposure to tobacco smoke containing lead and arsenic has not been determined. It is not likely that one could obtain a toxic dose of lead or arsenic from smoking one package or even several packages of cigarets daily; but because these toxic elements are cumulative, the possibility of the relationship of tobacco to poisoning with such heavy metals should not be overlooked.

WARTS AND MILKWEED

To the Editor:—I have been informed by several patients that the fluid which can be expressed from the stems and leaves of the milkweed has a curative effect when applied to verruca, or the common household variety of warts. I have seen this work to perfection in one case. Is there any known substance found in the milkweed or elsewhere which has this therapeutic property? In the case mentioned eight applications on alternate days caused the wart to disappear.

Oscar J. Hurak, M.D., Galetton, Pa.

ANSWER.—It is not likely that noncauterizing local applications have any direct effect on warts. In spite of the recent discovery at the University of California that milkweed juice contains a proteolytic enzyme, it seems unlikely that it can penetrate the horny armor of a wart. Until new light has been shed on this question it must be held that the milkweed juice treatment of warts remains in the controversial field discussed in answer to a query in *THE JOURNAL* Jan. 18, 1936, page 235. The skeptic claims that these cures are mere coincidences. The warts heal spontaneously at the proper time to give credit to the milkweed juice. The believers maintain that the spontaneous disappearance of warts does not occur with anything like the frequency with which cures by psychotherapy are effected by those who are adept at this treatment.

Dermatology waits with eager anticipation for the discovery of something in milkweed juice or elsewhere that will cure warts with certainty and without scarring.

CRANIAL NERVES AND CEREBROSPINAL SYPHILIS— ADIE'S SYNDROME

To the Editor:—In the course of my practice I have examined several patients who present signs which I have been taught are suggestive of siphylis of the central nervous system. Some have a history of previous siphylitic infection, others do not but admit likelihood of exposure. These signs are usually those of involvement of the cranial nerves, as evidenced by sluggish or fixed pupils, smooth forehead with inability to control "wrinkling," facial tremor and inability to control facial muscles, with perhaps some difficulty in repeating test phrases, and the like. I have made it a routine practice in these cases to obtain a spinal fluid examination, which is frequently entirely negative. I am convinced that these patients have some siphylitic involvement and am at a loss to account for the infrequency of corroboration in the spinal fluid. The blood Kahn reaction is sometimes positive and sometimes negative. These experiences have given rise to several questions in my mind: 1. How long after the signs of cranial nerve involvement appear does the spinal fluid show changes either characteristic or suggestive of siphylis? 2. May cerebrospinal siphylis exist with an entirely normal spinal fluid? 3. Is it possible that other diseases may cause cranial nerve involvement, and if so what is the chance that such involvement is due to other diseases rather than to siphylis? 4. I was recently informed by a fellow physician of a syndrome called "Adie's" syndrome, in which fixed pupils have been present from birth. I should like more information on this disease.

George B. T. Ribble Jr., M.D., Philadelphia.

ANSWER.—The signs mentioned, in the absence of other confirmatory neurologic evidence and in the presence of a negative serum reaction, are in themselves not sufficient evidence on which to base a diagnosis of neurosiphylis.

1. It is the rule that the spinal fluid is positive for evidence of siphylis before the cranial nerve involvements have appeared. In other words, cranial nerve involvements are frequently a manifestation of a meningeal type of neurosiphylis, in which the spinal fluid is usually strongly positive at the time of the appearance of the cranial nerve lesions and remains so for some years thereafter.

2. Cerebrospinal siphylis may exist with an entirely normal spinal fluid. The so-called burned-out tabetic is an example of

this finding. In fact, 5 per cent of patients who have tabes dorsalis belong in the so-called burned-out group; or, in other words, individuals who manifest classic signs of tabes but in whom the serum reaction is completely negative and who have never received antisyphilitic treatment. Of course, the patient in whom the tabes is "burned out" as a result of treatment is quite commonly seen.

3. Other diseases may cause cranial nerve involvement, such as residues of mild types of encephalitis.

4. Adie's syndrome is of unknown origin. The patient has dilated pupils, which do not react to light and only slightly to convergence. It is usually associated with absence or decrease in the deep reflexes. It is not related to syphilis; it is frequently a family characteristic and is not progressive and usually causes the patient no inconvenience.

FACIAL HYPERTRICHOSIS

To the Editor:—What is the cause, if known, and the treatment, if any, of facial hypertrichosis in an otherwise normal unmarried girl of 24? The patient's past history is essentially normal except for the usual childhood diseases and an appendectomy two years ago when, the patient assures me, only the appendix was removed. The menarche occurred at 14; the menses have since been regular, with minor variations of four or five days' duration, moderately profuse and without pain. The facial hair has developed since adolescence. It is soft, fairly long and most marked on the upper lip and chin. Physical examination reveals no other abnormalities except a masculine distribution of pubic hair. The external genitalia and secondary sex characteristics are entirely normal. The internal genitalia are said to be normal on pelvic examination. The girl's libido and interests are entirely female. The problem appears to be a cosmetic one. Any advice would be appreciated.

M.D., New York.

ANSWER.—The causes of facial hypertrichosis in the young woman are undoubtedly bound up in part with the state of the glands of internal secretion. Just which glands are most influential and the exact balance necessary among their secretions to produce these changes in the facial hair are not entirely known. Tumors of the cortex of the adrenal gland have been found in some patients with hypertrichosis. Enlargement of the adrenal gland, however, is not always present nor is the excretion from the cortex known to be increased in every case. Certain ovarian tumors may be associated with hypertrichosis.

A number of methods have been used for the removal of these hairs. The x-rays have been used, but, to be effective, this method requires doses beyond the safe tolerance of the skin. Dangerous sequelae are apt to occur some time after such treatment. At present, all responsible persons are emphatic in saying that x-rays should not be used for the epilation of facial hair for cosmetic purposes.

Several methods which are safe to use are bleaching of the hair with an agent such as hydrogen peroxide solution to make them less conspicuous, epilation with forceps, the use of an epilating wax and finally electrolysis. The electrolytic method properly done is a safe procedure and removes the hairs permanently. It is expensive, takes a long time and is somewhat painful. For many patients it is the most practical method.

ANAL SPHINCTER CONTROL AFTER OPERATION

To the Editor:—A patient had an operation for rectal fistula five months ago. The internal opening was high, above the external sphincter, necessitating a division of the external sphincter. This was done once, at right angles to the fibers. For a time she naturally had no control but as healing took place this gradually returned, though not completely. She came to the office recently, complaining of some lack of control. Examination of the anal area shows the normal puckering of the skin around this area. Rectal examination shows some sphincteric action, but not tight enough to be termed a normal control. What can be done to correct this condition and what are the prospects of the control coming back to normal without any further treatment?

M.D., Illinois.

ANSWER.—The external sphincter muscle is anchored by the sacrococcygeus muscle directly in the posterior line. The sphincter muscle may be cut in this line without a repair and there will usually be a good return of function. If the sphincter muscle is cut in any other quadrant and is not repaired immediately, there is usually enough retraction of the cut ends so that control of the sphincter is poor. If there is a hiatus between the ends of the muscle in the depth of the scar, the ends of the muscle should be dissected free from the enveloping scar tissue and each end of the muscle should be anchored to the bottom of the wound by mattress sutures so that the ends are approximated and cannot retract. In most cases this gives a good return of function. Function will probably not improve much spontaneously at this late date.

VACCINIA VIRUS IN EYE

To the Editor:—To what extent is the eyeball endangered following accidental splashing of potent smallpox vaccine into the eye? To what extent is this danger increased by superficial abrasion of the bulbar conjunctiva sustained about a week earlier? What besides irrigation would constitute prophylaxis? I am aware that bulbar involvement can occur in generalized vaccinia and is deliberately achieved in animal inoculations, as in Paul's test.

M.D., Arizona.

ANSWER.—Splashing of vaccinia virus into the eye may be classified as a vaccination injury or unintentional infection with vaccine. The infection may occur either with animal lymph or with human lymph from an accidentally ruptured pustule on the vaccinated person.

If the infection occurs in a susceptible person, the resulting pustule will resemble a primary vaccination. If the patient has been previously vaccinated, the lesion will assume the character of a revaccinal lesion.

In order that accidental vaccination may occur, an injury or a break in the skin or mucous membrane must be present.

Accidental vaccination as a lesion of the eye occurs most frequently in persons suffering with eczema. An eczematous palpebral margin is a favorite site for such a lesion. If the infection is confined to the palpebral margins, healing may take place without scar formation. However, if epithelial defects occur, involvement of the conjunctivas and cornea occurs also.

Prophylaxis against accidental vaccination should consist of refusal to vaccinate whenever such cutaneous conditions as eczema, impetigo contagiosum and other forms of dermatitis are present.

In a case of accidental splashing of vaccine into the eye as noted in the query, a prompt irrigation of the eye with physiologic solution of sodium chloride or sterile water would probably be the most suitable prophylactic measure which could be undertaken. Any traumatizing procedure which might injure the conjunctival epithelium should be avoided.

IRRADIATION OF ADRENALS FOR HYPERTENSION

To the Editor:—Please discuss irradiation of the adrenal glands for essential hypertension. I am sure a patient of mine has too much internal secretion from the adrenal glands, and treatment by x-rays ought to give as good results as irradiation of the pituitary gland for oversecretion. The patient is a man aged 48 of florid complexion and perfectly well in every way so far as study in a hospital can determine and it is a definite essential hypertension. While 30,000 units of estrin controls the blood pressure it does not cure the condition, and if we could decrease the adrenal activity I believe we can cure this man. Can you give any information relative to irradiation of the glands in question for such a condition?

O. F. McKittrick, M.D., Linglestown, Pa.

ANSWER.—The most extensive studies of irradiation to the pituitary and adrenal areas in hypertensive disease are those of Hutton (*Radiology* 24:330 [March] 1935; *Clinical Med. & Surg.* 44:533 [Dec.] 1937). Distinct and encouraging subjective improvement is reported in about one half of the cases so treated. The objective reduction of the arterial tension is less striking. What reduction does occur is usually quite temporary. These observations have not as yet been fully confirmed by other investigators.

The recommended dose is small. The results with larger doses have been definitely less encouraging. Larger doses induce headaches, vertigo and nausea, and the arterial tension is less effectively reduced. Each side of the pituitary was treated with 50 roentgens, 120 kilovolts, 2 mm. of aluminum filter, 50 cm. skin target distance, 3 milliamperes for five minutes. The adrenals were irradiated through a single portal of 15 by 15 cm. with the same exposure. Such irradiation, although small enough to assure against gross damage, should not be given more frequently than once a week or in courses over six consecutive weeks. In women this radiation therapy should never be administered closer than one week prior to an expected menstrual period. More frequent or more intense therapy is prone to fail even in carefully selected cases. Hutton recommends that the two sides of the pituitary and the adrenal area be irradiated on the same day.

Though these and a few other reports are suggestive that such radiation therapy, if properly controlled, may prove to be an adjunct in the management of hypertensive arterial disease, the data are inconclusive. The role of endocrine imbalance in the etiology and pathogenesis of hypertension is but poorly established. A diagnosis of hypertension as due to "too much secretion of the adrenal glands" seems hardly justified on the purely negative evidence implied in the present case. One does not share the conviction that this is so major a factor in the etiology. Hypertension may be provoked in many different ways and etiologic diagnosis is frequently difficult and laborious.

However, guesswork and assumption should be reduced to a minimum. The hypertension of adrenal adenomas is associated with characteristic episodes of crisis, with extreme variability of the tension. In so-called essential hypertension there is no convincing evidence that adrenal hypersecretion plays any significant etiologic part.

While radiation therapy in this or any other instance of hypertensive disease is not recommended, the small doses advocated by Hutton are apparently quite safe. The transient nature of the reduction of the arterial tension following such irradiation implies that the fundamental origin of the disorder has not yet been reached.

CELL COUNTS FROM OXALATED BLOOD

To the Editor:—Can the red and white blood cells be counted in oxalated blood? Can a differential white count be made? If so, how long can the blood be left before these counts are made? M.D., Tennessee.

ANSWER.—Red and white blood cell counts may be done with oxalated blood. One or two cubic centimeters of blood is drawn from a vein with a dry syringe and needle and placed in a small tube, a small medicine glass or a shallow Petri dish which contains a mixture of dry ammonium and potassium oxalate crystals. The blood is stirred well by gentle shaking to prevent clotting and clumping. Red counts and white counts made from a solution of this type are accurate for several hours after the blood is drawn but should be stirred gently immediately before the filling of the pipet.

For the making of smears for differential counts, blood obtained in this way probably is not as good as blood obtained from a puncture of an ear lobe or a finger. Oxalated blood has a tendency to cause slight pyknosis of the red cells as well as the white cells, and in particularly important cases there may be some difficulty in obtaining adequate detail in the various types of cells.

Frequently blood is drawn as a routine from a vein for a Wassermann test and a blood chemistry examination, and 2 cc. is placed in a separate vessel for the carrying out of a complete blood count.

Osgood recommends this method and finds it satisfactory both for cell counts and differentials. Many others feel that red counts and white counts may be done with accuracy on oxalated blood and for at least five or six hours after the blood is drawn, provided the fluid is kept at cool temperatures and that it is shaken well before the pipets are filled. Blood smears for differential counts should be made as soon as possible after the blood has been drawn into the vessel containing oxalate.

SODIUM AMYTAL DURING LABOR

To the Editor:—Relative to the administration of sodium amytal by rectum during labor, would you kindly inform me as to the following points: (a) How early in labor may it be instituted? (b) What is the dosage per injection? (c) What menstruum and what amount are used per injection? (d) What is the frequency of reinjection, safety being considered?

Joseph Liburt, M.D., Huntington, N. Y.

ANSWER.—(a) Sodium amytal may be given as soon as labor is definitely established. (b) Six or 9 grains (0.4 or 0.6 Gm.) should be given by rectum as the first dose. Three or 6 grains (0.2 or 0.4 Gm.) may be repeated one or more times if the first dose is insufficient or the labor is prolonged. (c) The sodium amytal may be placed in 4 ounces (120 cc.) of warm water and this mixture placed in the rectum. (d) It is safe to reinject sodium amytal at the end of three hours. However, all patients who receive this drug must be watched constantly and carefully, and the repetition of the treatment should not be a matter of routine but should depend on each patient's reaction to the drug.

INFESTATION WITH FILARIA LOA

To the Editor:—A patient stated that he had been on the west coast of Africa in 1935 and had contracted Filaria of the Loa loa species. He has evidences of subcutaneous nodules and burrowings, and nocturnal appearances of worms in the conjunctiva. He has removed and brought me the worms. Will you please tell me if there is any specific treatment for this type of Filaria? M.D., Illinois.

ANSWER.—None of the forms of chemotherapy have been strikingly successful in treating infestation with Filaria loa, though arsenamine and autimony and potassium tartrate have been tried. When the worms can be seen under the conjunctiva or skin they can often be removed. Application of heat may be useful to bring them near the surface. Some surgeons have been successful in injecting a local anesthetic into the worm or near it, paralyzing it so that it will not escape. In other cases

a suture is passed quickly beneath the worm through the conjunctiva or skin, or it is grasped by fixation forceps through the conjunctiva, after which it is removed through a small incision. This may have to be repeated a number of times, if several worms are present.

PARTIAL DESTRUCTION OF NAIL BED

To the Editor:—Because of a trauma, the distal half of the left thumb nail of a man is not adherent to the underlying tissues. He would like it remedied. If the surface of the underlying tissue should be denuded with acid or by mechanical means and a pressure dressing then applied, would the nail and tissue become adherent?

Hobart P. Shattuck, M.D., Los Angeles.

ANSWER.—Failure of a nail to adhere to the underlying tissues is invariably the result of injury and partial destruction of the nail bed. As a result of such injury this portion of the nail bed does not function in a normal fashion and does not take part in the formation of the growing nail.

To denude the tissues under the nail with acid or by mechanical means would simply cause further destruction and would be likely to result in an open wound, which would heal with difficulty and with formation of dense scar tissue. Unfortunately there is no logical reason for thinking that such a procedure would be of value.

PROBABLE SPRUE

To the Editor:—A white woman aged 50 has had aphthous stomatitis for the past two or three years, with oozing of blood from the tongue, which is sore and atrophic and beefy red. There is painful lymphadenopathy in the neck and a painful sensation in the epigastrium and chest. The gastric acidity is normal. The blood picture is normal: hemoglobin 80 per cent, red cells 4,400,000 and white cells 5,200. There is a yellowish tinge to the skin and she has had considerable liver therapy (parenterally) though the exact quantity is not known. The mucous membranes of the vagina present the same aphthae as noted in the mouth, and the cervix is red and beefy, oozing a bloody discharge on examination. The rectum presents a similar appearance. Cultures from the mouth and rectum on Sabouraud's honey agar medium produced a creamy growth in four or five days, and microscopic examination showed some type of Monilia. The patient states that she has large foamy and foul-smelling stools at times, but the stools do not present this appearance at present, though she does pass streaks of blood and mucus. The condition is painful and there are spontaneous periods of improvement. There has been considerable loss of weight, though she is still not emaciated, as she was formerly overweight. 1. Is this a case of sprue? 2. Does the finding of Monilia in any way substantiate the diagnosis of sprue? 3. If this is probably not sprue, what steps might be taken to arrive at a satisfactory diagnosis? 4. What type of treatment would be indicated for such a case? She has had liver in considerable quantity, numerous vitamins, especially B₂, pancreatin and hydrochloric acid, solution of parathyroid and calcium lactate. 5. Is the dextrose tolerance test of much importance in this condition? M.D., South Carolina.

ANSWER.—1. This most likely is a case of sprue. 2. The finding of Monilia is believed by some authorities to substantiate the diagnosis.

3. As given.

4. The treatment outlined is quite comprehensive. It is assumed that the patient has had a proper, well balanced diet, which did not contain any of the ordinary sugar and cereals and was also low in its fat content. It might be wise to try potassium iodide in ascending doses, principally for its alterative action.

5. The dextrose tolerance test is of no significance in this condition.

INOCULATION OF CARCINOGENIC AGENTS IN MAN

To the Editor:—A laboratory technician has been working on mice and carcinogenic substances, particularly dibenzanthracene, benzopyrene, methylcholanthrin and styryl. While working with these she was bitten by a mouse, and as her hands were quite covered with these substances she was rather thoroughly inoculated. Would you let me know the possible consequences of an inoculation of one or several of these substances. M.D., Massachusetts.

ANSWER.—There is no available evidence to indicate that a single inoculation of the carcinogenic agents mentioned will produce a neoplasm at the site of injury.

CARD PLAYING BY COLOR BLIND

To the Editor:—Can a person who is color blind play cards?

Robert Boyd, M.D., Brooklyn.

ANSWER.—In all card decks the suits are distinguished as much by the form of the pips as by the color. Even if the red cards appear as a drab gray (it does to a real trichromat), the intensity of the hue is sufficiently different from that of the black cards to permit recognition even if unaided by the shape of the pips.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, December 23, page 2344.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 12-14. Exec. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Part I. Various places throughout the United States and Canada, March 28. *Oral.* Part II. New York, June 10-11. Applications must be received 60 days prior to examination. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY: November 1940. *If a sufficient number of applications are received before March 1 there will be an examination at New York, June 10-14.* Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Feb. 19. Formal application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *General oral and pathologic examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 8-11. Applications for admission to Group A, Part II, examinations must be on file not later than March 15.* Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* Various cities of the United States and Canada, March 2. (The only written examination in 1940.) *Oral.* New York, June 8-10; Cleveland, Oct. 5. *Formal applications must be received before Jan. 1.* Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 3-5. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: New York, June 10-11. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Kansas City, Mo., May 18, following the Region III meeting of the American Academy of Pediatrics. Seattle, June 2. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF UROLOGY: Chicago, Feb. 9-11. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

National Board of Medical Examiners

The National Board of Medical Examiners reports that its certificate was awarded 485 applicants who were successful in the examination in part III, held during June and July 1939. The following schools were represented:

Oklahoma June Report

Dr. James D. Osborn Jr., secretary, Oklahoma State Board of Medical Examiners, reports the written examination held at Oklahoma City, June 14, 1939. The examination covered twelve subjects and included 120 questions. An average of 75 per cent was required to pass. Forty-three candidates were examined, all of whom passed. Twenty-seven physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

Book Notices

Cancer of the Colon and Rectum: Its Diagnosis and Treatment. By Fred W. Rankin, B.A., M.A., M.D., Surgeon, St. Joseph's and Good Samaritan Hospitals, Lexington, Kentucky, and A. Stephens Graham, M.D., M.S., F.A.C.S., Surgeon, Stuart Crele Hospital, Richmond, Virginia. Cloth. Price, \$5.50. Pp. 358, with 133 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1939.

This monograph is a model of authoritative statement on a subject in which the authors have had wide experience and therefore becomes an important contribution to the subject. While no particularly new points of view or methods are advanced, the authors have selected from the literature the most important contributions of English and American surgeons and have clearly depicted them and at the same time have elaborated their own experiences in an orderly and systematic manner. Splendid printing and illustrations on fine paper, easily readable tables, and thorough and detailed consideration of the many phases of the subject make the monograph invaluable to any surgeon interested in the subject. For the general medical man the monograph offers an opportunity to learn in an authoritative way the early symptoms, the diagnosis, procedures, the treatment and the prognosis of carcinoma of the rectum and colon. In view of the fact that about 40 per cent of deaths from cancer are due to cancer of the gastrointestinal tract and that 15 per cent are due to cancer of the bowel including the small intestine, it is obvious that this monograph covers a field that must appeal to every thoughtful medical man.

The chapter on operability and prognosis is an especially interesting one because in the first instance operability is often a matter depending on the experience and leanings of the individual surgeon and prognosis in turn depends much on operability and the careful estimation of the extent of the pathologic process. In this chapter, therefore, the reader is given a glimpse at the authors' judgment in selection of patients for operation and an estimation of the criteria which make for a long cure.

There are a few places in the monograph where exception to the views of the authors may be taken and in order not to make our praise of this work too florid, the relation of carcinomatous lymphatic involvement in prognosis can be mentioned; strictly speaking, lymphatic involvement is of most value in prognosis when the methods of determination and results of the study of lymphatic involvement are described. For instance, in the examination of removed specimens of cancer of the bowel for lymphatic involvement only twenty glands on an average can be removed and examined, contrasted to an average of from fifty to eighty glands which can be removed from the specimen after clearing it of blood and removal of the glands by means of transillumination. In the first instance, in which only twenty glands are examined, the involvement with cancer is about 45 per cent; when fifty or more glands are examined microscopically, the involvement is nearly 70 per cent. It is obvious that such a difference in the degree of involvement depending on the thoroughness of removal of the glands in a specimen will greatly modify the longevity figures which are based on lymphatic involvement.

The chapters on choice of operation, operative mortality and end results are excellent. The critical estimation of the results of others and the compilation of their own experience strike a high note in surgical writing.

Some of the high lights include the increasing tendency of experienced surgeons to remove cancer of the rectum by a one stage abdominoperineal procedure, the authors' abandonment of preoperative peritoneal vaccination, the value of resection of the left half of the colon by obstruction resection, and the five year survival figures in nearly 40 per cent of operable cases.

Were it possible to fill the racks of our medical libraries with medical monographs such as this one, the student of medicine would indeed be fortunate.

The Statistics of Pulmonary Tuberculosis in Denmark 1925-1934: A Statistical Investigation on the Occurrence of Pulmonary Tuberculosis in the Period 1925-1934, Worked out on the Basis of the Danish National Health Service File of Notified Cases and of Deaths. By Marie Lindhardt. Acta tuberculosa Scandinavica, Supplementum III. Paper. Pp. 179 with 17 illustrations. Copenhagen: Ejnar Munksgaard, 1939.

In this work attention is called to the fact that in 1896 the General Danish Medical Association requested the board of health to take steps to introduce obligatory notification of "pulmonary consumption" on physicians' weekly report lists and the inclusion of pulmonary consumption among the diseases for which free disinfection was obtainable. Because of certain objections on the part of the board of health it was not until April 1905 that Parliament passed two important tuberculosis laws, one of which dealt with the support of tuberculosis institutions by the state, and the other the Prevention of Tuberculosis Act, which provided for compulsory notification of cases of tuberculosis. Thus Denmark has had compulsory notification for all forms of pulmonary tuberculosis, with individual notification of every case and every death, continuously since 1905.

The present report is based on 41,704 notifications of fresh cases of pulmonary or laryngeal tuberculosis, in which there were 20,173 deaths. All of these deaths occurred in the ten year period 1925-1934. The cases are studied with reference to the various parts of the country from which they came and according to sex, age and occupation. Observations are also presented on the duration of cases that proved fatal.

It was pointed out that both morbidity and mortality are highest among females and that in both males and females the morbidity and mortality was highest in the age group of 20 to 24 years. For the entire country during the decade of 1925-1934, approximately one third of all deaths among males in the ages of 20 to 29 were due to pulmonary tuberculosis, whereas among females it was about one half between 20 and 24 years. Of all deaths in the decade, three fourths occurred on an average of eighteen months after notification for both sexes.

This volume contains numerous tables and curves, which are of great value to those interested in this particular phase of tuberculosis work. A valuable reference list is included.

The Health Insurance Doctor: His Role in Great Britain, Denmark and France. By Barbara N. Armstrong. Cloth. Price, \$3. Pp. 264. Princeton, N. J.: Princeton University Press, 1939.

The blurb on the jacket says of the author "She was formerly executive secretary of the California Social Insurance Commission and for more than two decades has campaigned vigorously for health insurance." While this bias is evident in many places, no other book gives as detailed and accurate a survey of the British, Danish and French systems of sickness insurance.

The figures as to the percentage of physicians engaged in panel practice are a little hard to reconcile with those given in the "Report of British Health Services" by PEP (Political and Economic Planning). "The drugs capitation fee is uniform for all areas" and in 1936 this was set at 56 cents per head if all drugs were supplied. In view of the complaints of "excessive prescribing" this seems a very inadequate sum if really necessary drugs are supplied.

The statement is made repeatedly that physicians do not object in any of these systems to certification for inability to work, and there is considerable effort to show that certification causes but little conflict. The reader can draw his own conclusions from the description of the elaborate machinery that is maintained at least in Great Britain and France on the side of both the medical and the insurance carriers to hunt out abuses of certification. The conflicts in the French system between the insurance carriers and the physicians is emphasized, but little attention is given to the extent to which this is due to the participation, in spite of the law, of the carriers in the control of medical service or that this conflict is largely over certification for cash payments.

"For completeness of medical benefits," says the author, "Denmark with nearly fifty years of health insurance behind her stands out conspicuously in the three systems of health insurance review." That this superiority is due to the almost complete domination of the Danish system by the Danish medical association receives no emphasis, although the facts are accurately stated. Neither is there any stress laid on what

would seem to be a highly significant fact—that the Danish system is not really an insurance system since hospitalization, which is much more frequent than in most countries, is paid for largely by the state and local communities, which also pay much of the cost of insurance. Only members of the Danish Medical Association can engage in insurance practice, and the control of medical practice is almost entirely in the hands of the professional association. Moreover, no mention is made of the fact that during all but the last eight of the fifty years existence of the Danish system it was a voluntary system.

If the bias of the writer, which seems to be inseparable from all descriptions of sickness insurance, is kept in mind, this book is a valuable source of reference, especially on the details of organization, for any one interested in the subject of sickness insurance.

The Patient as a Person: A Study of the Social Aspects of Illness. By G. Canby Robinson, M.D., LL.D., Sc.D., Lecturer in Medicine, Johns Hopkins University, Baltimore. Cloth. Price, \$3. Pp. 423. New York: Commonwealth Fund; London: Oxford University Press, 1939.

This book should be carefully studied by general physicians and medical specialists of all fields. Written by an internist of great reputation, it adds new emphasis to the social aspect of illness. The author has studied in cooperation with social workers 174 patients suffering from a wide variety of diseases. He describes in succinct abstracts the illnesses and the environmental factors involved, so that the total picture of patient, disease and social factors are clearly visualized. The evidence is so well presented and the conclusions are so important for modern medicine that the volume could be made the text from which a special course might be taught in medical colleges. Concerning recent trends in governmental circles the following is quoted: "If the proper relationship of doctor and patient is retained through thick and thin, and the patient is given adequate consideration as a total individual, medical service will not suffer, no matter whatever the methods of organization, distribution and payment and whether or not the patient has a free choice of doctors beyond narrow limits. And it is the preservation of this relationship which new plans of medical service threaten that should be the keynote of the conservatism of the medical profession. If the medical profession is to give its best to the public which is now demanding changes in its medical service by legislation and government control, the so-called art of medicine must not be swept away by the waves of reform and of social reorganization. . . . The true physician must know his patient as an individual.

Fifty Years a Doctor. By John Kercher. Cloth. Price, \$2. Pp. 247, with 15 illustrations. Boston: Meador Publishing Company, 1939.

Here are numerous incidents in the career of a physician who has practiced fifty years. He recounts the difficulties of getting started in practice in Chicago and notes that his office at one time was right next to that of Frank Billings and Herman Spalding, at the corner of Jackson and State streets, where the Hub clothing store is at present. He recounts his experiences in joining a group organized by his brother-in-law, a captain in the Chicago Fire Department, to go to the Klondike to seek gold in 1898. The book has little scientific or literary value.

Spezielle Symptomatologie und Diagnose innerer Erkrankungen in zwei Bänden. Von Professor Dr. Gottfried Höller, Vorstand der III. Medizinischen Abteilung im Allgemeinen Krankenhaus in Wien, und Dr. Robert Pfleger, Assistant der Abteilung. Mit einem röntgenologischen Anhang von Primararzt Dozent Dr. Rudolf Pape. Bände I und II. Cloth. Price, 45 marks. Pp. 592; 593-1256, with 109 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1939.

This is another book on diagnosis in which the basis of the discussion is a symptom either subjective or objective in character. The whole subject of internal medicine is covered. The reader looks in the index for the symptom which is most prominent and is referred to the location in the text for a differential diagnosis of the subject in which he is interested. While the subject matter is fairly good, it is rather inadequate and needs further elaboration. The experience of the reviewer in trying to obtain information on several subjects does not lead him to believe that it has any more value than as a guide. For further information, other sources of information must be consulted. There are numerous illustrations and a good index, and it is well printed.

Les erreurs et les fautes en urologie: Etude critique, clinique et thérapeutique. Par L. Strominger, docteur d'urologie à la Faculté de médecine de Bucarest. Préface de M. le Prof. G. Marion. Paper. Price, 45 francs. Pp. 176. Paris: Masson & Cie, 1939.

In this monograph the author considers the errors which are not infrequently made in the diagnosis, prognosis and treatment of urogenital conditions. The introduction, written by Professor Marion, has as its main theme the fact that "we learn more through our errors than through our successes." The book is filled with urologic wisdom which only a man with a wide practical experience could have acquired. He warns against the indiscriminate routine use of the cystoscope because of the damage which can be caused by it. He reminds the reader that appendectomies have frequently been performed erroneously in cases in which treatment should have been given for uterine and vesicular inflammation. The value of the book lies quite as much in its repetition of important errors which have been mentioned by other writers as in its presentation of new material. It emphasizes the things we have already learned and may forget and, in addition, it teaches valuable lessons that we should have known. The entire urogenital tract is systematically covered, beginning with renal disorders, proceeding to the ureters and bladder, and concluding with the genital organs. The book ends with a presentation of errors in radiology, which every surgeon and urologist should read because of its importance. The bibliography, while rather extensive, is limited to the works, mostly French, consulted by the author. A careful study of this valuable volume will help the reader to avoid many snares and pitfalls, with their occasionally unhappy consequences.

The Harvey Lectures Delivered under the Auspices of the Harvey Society of New York 1938-1939. Under the patronage of the New York Academy of Medicine. By Dr. Guy F. Marrian et al. Series XXXIV. Cloth. Price, \$4. Pp. 279, with illustrations. Baltimore: Williams & Wilkins Company, 1939.

This volume contains the following lectures: Guy F. Marrian, University of Edinburgh, aspects of the intermediary metabolism of the steroid hormones; A. Ashley Weech, College of Physicians and Surgeons, New York, significance of the albumin fraction of serum; Eugene F. Du Bois, Cornell University Medical College, heat loss from the human body; Edwin J. Cohn, Harvard Medical School, proteins as chemical substances and as biologic components; Edwards A. Park, Johns Hopkins University, pathology of rickets with particular reference to the changes of the cartilage-shaft junctions of growing bones; K. Linderström-Lang, Carlsberg Laboratory, Copenhagen, distribution of enzymes in tissue and cells; C. H. Danforth, Stanford University, genic and hormonal factors in some biologic processes; Albert Szent-Györgyi, University of Szeged, biologic oxidation and vitamins.

Studien über experimentelle arthritiden und Karditiden. Ein Beitrag zur Frage der pathogenetischen Bedeutung endokriner Faktoren bei dem sogenannten Gelenkrheumatismus. Von Eric Jonsson. Acta medica Scandinavica, Supplementum C. Paper. Pp. 122, with 35 illustrations. Stockholm: Tryckeri A.-B. Sätterlund & Krook, 1939.

This is a short monograph on the relationship between endocrine dysfunction and arthritis. The author presents a historical review of the literature on the endocrine and arthritis relationship, which he summarizes to the effect that the endocrine disturbance is either the only cause of the joint symptoms, or a predisposing factor, or a coordinated one. Exclusive endocrine etiology is declined but the predisposing factor and the coordinated character are given the benefit of doubt from the review of the literature. The original work of the author is directed toward the solution of the question how far animal experiments will reveal the causal relation between endocrine disturbance and arthritic symptoms. The experiments of the author include serum and tuberculin injections, inoculation with streptococcus and polymorphodiplococcus, and foreign protein injections, applied to castrated animals as well as to controls. The conclusion of the author seems to be that the results indicate that endocrine influences exist in castrated animals; they have a part in the pathogenesis of certain forms of joint rheumatism, are not of dominant significance, and can be considered only as a predisposing factor. This seems to be all that is brought out in this rather short but well written and clearly presented monograph.

Les calculs de l'urètre. Par Pierro Maequet. Préface du Professeur G. Potel. Paper, 45 francs. Pp. 187, with 22 illustrations. Paris: Masson & Co, 1939.

In this monograph the ureteral calculus is dealt with from the purely clinical point of view. The work is based primarily on the personal experience of the author, who for many years was assistant and chief of clinic under Prof. Gaston Potel. The latter has written a laudatory preface. Throughout the work emphasis is placed on the potential damage which the ureteral calculus can inflict on its associated kidney and the imperative need for its early removal from the urinary tract in order to prevent or minimize this damage. Jeanbrau, credited with having done the first important work on the ureteral calculus, is quoted as saying "The renal calculus often can wait; the ureteral calculus cannot wait." The author emphasizes this dictum throughout the work. Diagnosis and therapy occupy the major portion of the book. Little or no reference is made to the etiology of calculus or of the role which infection may assume. The illustrations are excellent and indicate well what they are intended to show. Twenty-seven cases of ureteral calculus are reported in detail. The work ends with an extensive bibliography covering the last thirty years.

The Management of Tuberculosis in General Hospitals: Patients, Staff, Employees. Prepared by William H. Oatway Jr., M.D., Assistant Professor of Medicine, University of Wisconsin Medical School, Madison, for the Council on Professional Practice of the American Hospital Association. Cloth. Price, \$1. Pp. 78. Chicago, Illinois: American Hospital Association, [n. d.].

This work fills a long felt need, since there has not previously been available any outline of procedure for the management of tuberculous patients in general hospitals. Dr. Oatway was unable to find any hospital in the entire nation that has at present a complete tuberculosis program. The use of general hospitals for the isolation and treatment of tuberculosis has been recognized by a number of national and international medical and health organizations. As early as 1908 the International Congress on Tuberculosis, which met in Washington, D. C., urged the care of tuberculous patients in general hospitals. In 1912, and on a number of occasions since, the National Tuberculosis Association has made similar recommendations. The American Medical Association in conjunction with the United States Public Health Service in 1920 recommended the provision of wards in general hospitals for the care of tuberculous patients. The Canadian government has urged that hospitals receiving government aid hold available 10 per cent of their beds for tuberculous patients. Many physicians expert in the field of tuberculosis have strongly recommended the use of general hospitals for tuberculous patients, such as the late Dr. Lawrence Flick, of Philadelphia, who in 1895 arranged for such beds in general hospitals.

The author presents twelve reasons why general hospitals should admit tuberculous patients. He emphasizes the educational effects of having tuberculous patients in general hospitals for the medical staff, including interns and students, and also the nursing staff, including students.

He also calls attention to certain objections that have been offered to the hospitalization of tuberculous patients, but he states that there is apparently no logical reason for not admitting such patients, provided the danger of infection is controlled by thoroughly modern procedures. Dr. Oatway emphasizes the danger of infection to other patients and the entire personnel of the hospital and shows that for 120 years the high incidence of tuberculosis among nurses has been under discussion. He then proceeds to show how hospital personnel as well as other patients can be protected against exposure. It is strongly recommended that all members of the personnel of the hospital be adequately examined periodically for tuberculosis and that all patients admitted to any hospital be examined for tuberculosis in contagious form regardless of the condition for which the patient was admitted. When persons with contagious tuberculosis are found in the personnel or among the patients, a provision is recommended for them in which a technic is practiced in an attempt to control the spread of the disease. Thus the environment of the hospital is rendered free from contagious tuberculosis except in a small section set aside and equipped to manage such cases properly.

The last twenty pages of this book is devoted to an outline of a program for management of tuberculosis in a general hos-

pital. This is prepared in such a manner that any one who reads it can find all the information necessary for setting up a tuberculosis service in a general hospital and managing the control of this disease throughout the entire institution. The author of this book, the American Hospital Association and especially the Council on Professional Practice are to be congratulated on publishing and distributing such a timely volume. An extensive list of references greatly enhances its value.

Psychiatrie: Ein Lehrbuch für Studierende und Ärzte. Von Prof. Dr. Kurt Koller, Nervenarzt in Frankfurt a. Main. Paper. Price, 13 marks. Pp. 415, with 5 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1939.

This is just another compilation of clinical data labeled psychiatry by a practicing specialist for students and physicians. It is interesting that in this German volume published in 1939 there is a large section devoted to military questions. The book has no value.

The Stale and Medical Research. By Sir Edward Mellanby, K.C.B., M.D., F.R.C.P., Secretary, Medical Research Council. Harvelan Oration, Royal College of Physicians, 18th October 1938. Cloth. Price, 3s. 6d. Pp. 52. Edinburgh & London: Oliver & Boyd, 1939.

The permission given William Harvey by Charles I to make use of deer and other animals in the royal parks for investigative purposes is held to be probably the first instance of state support of medical research. Support of research is discussed, particularly as illustrated by the Medical Research Council in England, which of late has been receiving an annual grant of £195,000 from the government. The organization and the activities of the council form the main part of the lecture, which will be read with interest by those who are concerned with administration of research.

Hormones and Resistance: An Acute Antinarcotic and Antitoxic Effect of the Estrogenic Hormones. By Tore Patrik Störtebecker. Acta pathologica et microbiologica Scandinavica Supplementum XXI. Paper. Pp. 294, with 4 illustrations. Copenhagen: Ejnar Munksgaard, 1939.

The author has presented his experiments on the antinarcotic and antitoxic aspects of the estrogenic substances and on the sex variation in resistance to various poisons and anesthetics. He has concluded that estrogens protect the animal against these substances to a varying degree. Much of the material should be confirmed, since there are relatively few data in the literature on this subject. The practical importance of this work is still to be demonstrated.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Infection Following Childbirth Not Proof of Malpractice.—Sept. 2, 1935, one of the plaintiffs employed Dr. Clark, a member of a medical clinic, to attend his wife during confinement. Dr. Clark was called in an emergency, the patient's family physician not being available, and arrived a few minutes after the baby was born. He tied off, cut and bandaged the umbilical cord. He delivered the afterbirth and examined it in a general way. He cleansed the patient's external genitalia and caused sanitary pads and bandages to be prepared and used. He instructed the patient's mother to bathe the patient with a compound solution of cresol and water. On departing he gave no instructions other than a schedule for the baby's feedings and advice that the mother be given light food.

According to attendants, on September 3 and 4 a fever developed and a lump was noted in her side, but although Dr. Clark visited her on those days he made no examination, not even taking her temperature or pulse. Later she had pains in her side, headache and an offensive vaginal discharge. On the evening of September 4 the patient became worse and, in the absence of Dr. Clark from the city, another member of the medical clinic was called, but he did not visit her until the following morning. Then he did not take her temperature

with a thermometer, did not take her pulse and made no physical examination other than to examine her throat. He told her she might have scarlet fever and prescribed acetylsalicylic acid and quinine and advised warm soda water and alcohol baths. From September 5 to 10 the patient had a high temperature and an increasing pulse rate. Dr. Clark saw her on September 6 and 7 and ordered the quinine that had been prescribed by his associate discontinued, but he did not examine her.

On September 10 another physician was called, one apparently not connected with the medical clinic with which Dr. Clark was connected. He found that the patient had a temperature of 104 F. The next morning he made a vaginal examination and, according to the patient's mother, removed a piece of the afterbirth, about 3 inches (7.5 cm.) in length, $1\frac{1}{2}$ inches (3.8 cm.) in width and $\frac{1}{2}$ inch (1.3 cm.) in thickness, and also "a clot of something white." The patient's mother claimed that she observed a tear in the right side of the patient's vagina. The patient died September 12. The death certificate issued by the physician last in attendance gave as the cause of death "Child Birth followed by Septic Toxemia (Streptococcus)."

The husband and the children of the deceased woman brought suit for malpractice against the defendant physicians Dr. Clark and his associate in the medical clinic. From the judgment of the trial court directing a verdict in favor of the defendants, the plaintiffs appealed to the Supreme Court of Utah. In their complaint, the plaintiffs based their charge of negligence on the following facts: 1. Dr. Clark did not carefully examine the placenta and therefore failed to ascertain that a portion of it had not been expelled. 2. Dr. Clark failed to discover and treat an alleged laceration of the patient's vagina. 3. Dr. Clark and his associate member of the medical clinic failed to take the patient's temperature or pulse or to make any examination other than to examine her throat, and therefore failed to diagnose and treat her for the condition from which she was suffering. The evidence presented, however, said the Supreme Court, was not sufficient to require the submission of the case to the jury.

The testimony of the medical witnesses called by the plaintiffs contained little in support of their own charges but did support the defendants' defense. Two medical experts testified that a general examination of the placenta such as was made was a proper examination and was such as an average physician of reasonable care and skill in that community would have made. Another witness testified that a physician, even after a most careful examination of the placenta, might fail to discover that a portion of the afterbirth had not been expelled and that the defendants' treatment conformed to the practice of ordinary, careful and skilful physicians in the community. Women die from puerperal fever, an infection which may come either from the blood stream of the patient or from the outside, in spite of anything that the physician or nature can do. Patients with "septic toxemia, due to streptococci or otherwise," he testified, are treated symptomatically or expectantly by rest in bed, reduction of fever, general care and alleviation of symptoms. Alcohol baths and the administration of acetylsalicylic acid and quinine would, in his opinion, be good treatment.

The fact that there was an offensive vaginal discharge or lochia, it was testified, did not in and of itself indicate that there was anything wrong. In the absence of lacerations or tears of the birth canal visible from the outside, it would not be considered good practice in that community, this physician testified, unless the patient were in a hospital where aseptic conditions could be obtained, to explore the birth canal by instrumentation or otherwise to determine whether internal tears were present or whether any portion of the placenta remained in the uterus. Even if the patient were in a hospital it was generally accepted as good practice in that community to refrain from exploring the birth canal unless some unusual condition appeared, such as a severe hemorrhage. The danger of such exploration may be greater than that of leaving to nature the care of any internal condition which may exist. Failure to take the pulse and temperature and to examine the patient otherwise than was done might be consistent, according

to medical testimony, with good practice in that community, or it might be bad practice, depending on the circumstances. The ordinary skilled and careful physician, it was testified, could determine the condition of his patient by observation without taking the temperature or pulse. The taking of the temperature or pulse did not constitute treatment, and failure to take either of them did not make the condition of the patient better or worse.

The doctrine of *res ipsa loquitur*, that the event speaks for itself, said the Supreme Court, has no application in this case. To recover damages, the plaintiffs had to show that the cause of the injuries complained of was the failure of the defendant physicians to exercise such care and diligence as was ordinarily exercised by skilled physicians in the same field of medicine in that vicinity. The court was unable to find anything which the defendant physicians had done that the evidence showed they should not have done or failed to do anything that the evidence showed they should have done. The expert medical testimony showed that the practice of the defendant physicians and the treatment prescribed by them was in conformity with that of the ordinary skilful physician in the community. Neither the testimony of lay witnesses nor that of expert medical witnesses pointed to any act of commission or omission on the part of the defendants that was the proximate cause of the patient's death. Although the testimony of the patient's father, mother and husband might have given rise to an inference that all was not done that in their minds they believed should have been done, the testimony that they gave did not indicate just what it was that they had in mind that should have been done.

In the opinion of the Supreme Court of Utah, the trial court properly refused to submit the cause to the jury, because to do so would improperly set the jury to conjecturing, surmising or guessing at the possibilities as to what should or should not have been done. Accordingly the court affirmed the judgment directing a verdict in favor of the defendant physicians.

One of the justices, however, Justice Wolfe, in concurring in the decision of the court, added the following interesting commentary:

I do not think that the rule that the testimony of a witness is no stronger than is shown by the cross examination applies in the case where cross and direct examination are practically reversed. Where it becomes apparent that a witness, while not hostile, is very reluctant to testify against a friend or one of his own profession, or is desirous of aiding him as far as possible by "going easy," or makes his answers all comport with a protective motive in the realm where opinions might differ, or gives him every benefit of the doubt in testifying that such conduct "might be good practice" or testifies with apparent mental reservations and simply awaits the cross examination to emphasize this protective motive, I do not see that the rule applies.

"It is not the duty or right of this court to appraise the evidence except to determine whether there is any substantial evidence to support the verdict or findings. If the opinions of the doctors who testified, as to the defendants' conduct that it was in conformity with the usual skilful practice under the conditions of this case in their community, appear to the layman to put that practice in that community on too low a level, the judicial finding of that fact must rest with the jury and not with this court. If the opinion means to hold by implication or otherwise that all negligence based on conduct of a doctor in an obstetric case must be proved by expert medical testimony, I do not agree.

—*Edwards v. Clark (Utah)*, 83 P. (2d) 1021.

- Western Section, American Laryngological, Rhinological and Otolological Society, Los Angeles, Jan. 26-27. Dr. Pierre Viole, 1930 Wilshire Blvd., Los Angeles, Chairman.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Ligation of Cord and Erythrocyte Count of Infant.—

In determining the relation of the erythrocyte count of the newborn and the time at which the cord is ligated, Frischkorn and Rucker at varying intervals tied the cords of more than 400 unselected infants. All the patients were white and all had sodium amytal-scopolamine analgesia and ether anesthesia. The cord continued to pulsate longer than in Budin's series, in which probably no anesthesia was used. In one instance pulsations continued for fifty minutes. The amount of blood that drained out of the placental end of the cord was measured. A blood count was made by the hospital technician within twenty-four to thirty-six hours. In fifty-nine cases in which the cord had ceased to pulsate before it was tied the infant's erythrocyte count averaged 5,783,400, whereas in 333 cases in which the cord was pulsating when tied the count averaged 5,198,919, a difference of 584,481. There was practically no correlation between the number of minutes that elapse before the cord is ligated and the erythrocyte count of the infant. The length of time before tying the cord had no influence on the amount of blood left in the umbilical vessels. On the other hand there is a significant negative correlation between the amount of blood that is left in the umbilical vessels and the number of erythrocytes in the infant's circulation. Those infants whose cords were allowed to stop pulsating before they were ligated had higher erythrocyte counts. This is significant enough to justify waiting until the cord ceases to pulsate and the umbilical vessels collapse, especially in small and premature infants.

Prolapse of Uterus, Hydronephrosis, Hypertension.—Wosika and Maher studied the relationship between the urinary tract and hypertension in fifteen cases of prolapse of the uterus encountered in private cardiac practice. Urologically, the patients presented variable x-ray changes by retrograde catheterization and intravenous urograms, from normal conditions to massive dilatation of the ureters and renal pelvis. Urethral and bladder irritation were invariably constant with evidence of infection, usually with *Bacillus coli* and staphylococci. From the cardiovascular standpoint, hypertension was present consistently with varying levels in all cases with the possible exception of one of extreme uremia and shock due to the incarceration. Evidence of left ventricular enlargement was present in from mild to extreme degrees, as shown by 2 meter roentgenograms. The electrocardiogram showed left axis deviation to be present in ten cases and normal axis deviation in five. Cardiac complications included congestive heart failure, coronary sclerosis and cerebral thrombosis. An associated study of the incidence of hypertension in a somewhat larger series of patients with prolapse was made possible through the records of the first eighty-four patients with prolapse entering the Passavant Memorial Hospital. Hypertension was found to be present in sixty-one of the eighty-four cases. The frequency of hypertension in these cases would indicate strongly that the occurrence of increased blood pressure and prolapse cannot be explained solely on a basis of coincidence. Factors commonly associated with increased blood pressure such as age, heredity and chronic nephritis were considered. The urinary observations were not characteristic of chronic glomerulonephritis, although transient albuminuria and casts were found in those patients who were observed over a period of years. The urologic evidence pointed to the infectious and obstructive character of the renal lesion rather than to a true glomerulonephritis. It was impossible to obtain evidence which either proved or disproved the hereditary factor. The damage to the urinary tract was found to be varying degrees of hydronephrosis and hydro-ureter, with recurrent infection. While the exact mechanism of ureteral compression does not seem to be entirely clear, obstruction is consistent with complete prolapse. While obstruction of the ureters was established readily with the complete prolapse, not all patients could be proved as having a resultant hydronephrosis and hydro-ureter by present day criteria. Generally, patients having prolapse of short duration had minimal urologic changes, while greater deformity was present when the procidentia existed for an extended period of time. Theoretically, it is possible for urinary obstruction, regardless of the cause, to produce hypertension. The role of obstruction in the production of hydronephrosis has been established. The role of infection also must be considered as a factor. The diagnosis of essential hypertension or hypertension of unknown origin is not justifiable unless all defects of the urinary tract are excluded. It seems that a perfect mechanism exists for the production of hypertension in patients with prolapse of the uterus, when the obstruction in the urinary tract produces hydronephrosis. The enlargement of the pelvis of the kidney encroaches on the blood supply. The partial ischemia that results produces systemic hypertension by an unexplained mechanism.

Abscesses and Diverticula in Female Urethra.—Schmitz and Nelson state that diverticulum of the female urethra, once considered rare, is now a not unusual diagnosis after careful gynecologic or urologic examination. More than 100 cases have been reported, and additions are rapidly being made. The authors cite eight cases. They are not to be confused with abscesses or cysts of Skene's glands, vaginal cysts or small vaginal myomas. Urethral diverticula may be classified either as true or as false. When all the layers of the urethra are involved in the process, they are called true diverticula. False diverticula are those in which only the submucosa and mucosa protrude, the muscularis having ruptured. Structural weakness, trauma and infection are important etiologic factors in acquired diverticula. Congenital diverticula are disputed. Treatment should be surgical extirpation. Suprapubic cystostomy is usually unnecessary. Use of the electrocautery is dangerous and may lead to poor end results.

Removal of Iodized Oil After Myelography.—Briesen believes that the procedure which he used for removing iodized oil after myelography dispenses with one of the major objections to performing myelography. After x-ray examination was done and the roentgenograms were developed his patient was taken to the operating room in a sitting position. With the area under local anesthesia an incision was made over the upper spines of the sacrum, the interspinous ligament was removed, a drill hole of one-eighth inch was placed in the sacrum and a trocar was inserted. No material would flow through the trocar, but when the trocar was removed the oily material flowed slowly, like cold syrup. Nothing seemed to hurry it. However, by means of a small probe and by allowing the material to run over the wound and into a cup, it was kept flowing until spinal fluid was obtained. The spinal fluid was allowed to run until there appeared to be no more globules of oil in it. The wound was then closed in a routine manner. The length of time that it took for the iodized oil to run out was approximately one hour, and consequently the patient suffered considerable pain and discomfort, as he was sitting up all this time. His recovery from this procedure was uneventful, and roentgenograms taken several days later showed at least a 90 per cent removal of the iodized oil. The author states that on inquiry as to the complete removal of the oil Adson suggested: "Have the patient sit upright in a chair for an hour before proceeding with its removal in order that all the lipiodol will be concentrated in the caudal sac. The operating table is then adjusted so that the head of the table is much higher than the foot, after which the patient is placed on his abdomen with the feet resting against the foot piece and the hands strapped along the side. In such a position, the lipiodol is constantly kept in the caudal sac."

Local Vitamin A for Ocular Disorders.—The local application of vitamin A in the treatment of injuries to and trophic conditions of the cornea is outlined by de Grösz. The vitamin A preparation is called vulnovitan (an oil or an ointment with petrolatum base) and 1 cc. of the oil contains 1,000 international units of vitamin A. As far as injuries are concerned, this therapy is extremely useful in promoting epithelization of fresh corneal lesions (as in erosions after extraction of foreign bodies) and it has a powerful analgesic effect, though it does not surpass ethylmorphine hydrochloride. The eye is bandaged. For injuries of the eyelid for which sutures are not necessary, the ointment (1 Gm. contains 500 international units of vitamin A) is used. Other conditions for which the ointment is indicated are torpid ulcerous and scrofulous blepharitis, though for the former a better reaction is obtained with roentgen irradiation. Though one cannot expect the anti-infectious factor of vitamin A to have a disinfecting action since it is not bactericidal, there is a rise of local resistance. However, if infection is feared or if signs of infection are already present, disinfecting agents should be used and foreign protein (milk) injected or sulfanilamide given. The vitamin A preparation has a good effect on injuries and burns of the conjunctiva, for after thorough rinsing of the culdesac its application prevents the formation of adhesions by hastening epithelization of the conjunctiva. The author has used vulnovitan (oil) for the treatment of caustic burns caused by lime and sodium hydroxide and also for injuries caused by indelible pencil, the eye first being rinsed with a 1 per cent solution of hydrogen peroxide. He states that vulnovitan is absolutely indicated for injuries due to gases used in industry and in warfare because of its analgesic and lubricating effect. Some of the other conditions in which he found vulnovitan to be beneficial are corneal inflammation, torpid ulcers, recurrent erosion, bullous keratitis, neuroparalytic keratitis, Fuchs's epithelial dystrophy, filamentous keratitis, corneal degeneration of obscure etiology, acute photo-ophthalmia, superficial punctate keratitis, radium necrosis of the cornea, keratitis due to mustard gas and trachomatous pannus. There is no indication for vitamin A therapy for acute or chronic catarrh, scleritis or deep keratitis. Local application of vitamin A not only helps but accelerates epithelization; it is truly a protective agent for the epithelium. The rise of the resistance is only a secondary phenomenon. To eliminate tolerance, over-dosage must be avoided. Vitamin A in oil should be purchased in small amounts (ampules) because, owing to its unstableness, it readily loses its effectiveness as the result of oxidation, once the container is opened. The excipient itself also has adhesive and protective characteristics. The use of ethylmorphine hydrochloride is not superfluous when one is applying vitamin A. The vitamin A is applied from three to five times a day and can be used with or without a bandage; a supplementary treatment can be given also. Heat in the form of short wave irradiation and infra-red irradiation should be given to aid resorption of vitamin A.

Beta Rays of Radium for Ocular Tuberculosis.—Woods used the beta rays of radium for the treatment of ten patients with tuberculous kerato-iritis and of three with deep tuberculous scleritis. There was prompt subsidence of all inflammation after one course of treatment, although two of the patients

with tuberculous keratitis had recurrences. These were again controlled by further irradiation. Deep scleritis was more resistant, steady treatment over a greater period of time being required before any decided improvement occurred. One patient showed improvement and final healing of the scleritis after steady treatment for eight months. The second patient, who was blind in one eye because of an atrophic choroiditis, had a marked scleral ectasia at the site of the scleritis. Under repeated courses of beta irradiation, extending over two years, there was definite and steady improvement with almost complete subsidence of the ectasia. This patient had been under observation for the preceding five years and had grown steadily worse in spite of all local and general treatment, including repeated paracentesis and tuberculin therapy. The third patient showed temporary improvement after only one course of treatment but had a relapse on returning to her home in a distant state.

Bilateral Detachment of Retina.—According to de Rötth, from January 1930 to June 30, 1938, there were 270 patients treated for retinal detachment at the State Eye Hospital in Budapest. Only a few of them have not been subjected to operation. Of thirty-three, or 12.2 per cent, the detachment was bilateral; twenty-three were men and ten women. The average age of patients when detachment developed in the first eye was 39 years and in the fellow eye 44. Forty-two per cent of the patients were young persons up to 30 years of age. Every type of retinal hole was observed, but each eye always showed the same type of hole as its fellow. In addition to the type being the same, the holes occurred mostly at a symmetrical part of the retina. The occurrence of binocular detachment, especially its uniformity in the two eyes, supports the view of Vogt concerning the pathogenesis of this disease, that disposition to develop a hole is a consequence of presenile and senile degeneration of the retina, vitreous, choroid and vessels. The disposition is a congenital property of the germ plasma. The author goes further and considers one group of binocular detachments as a primary heredodegenerative disease which does not depend on senility. The probability of heredodegeneration is supported by the occurrence of familial detachment in two brothers and a sister. The disease seems to be caused by abiotrophy—heredodegeneration of the retina, as in systemic degeneration of the nervous system. The retina as a portion of the central nervous system may also have a predisposition to degeneration lying in the genotype. The horseshoe-shaped or lobular holes are almost always combined with myopia and with degeneration of the vitreous. In these cases the mechanical effect, pulling by the vitreous, may also be a factor aside from the degeneration of the retina. In the small degenerative round holes a vascular degeneration is mostly present, i. e. a condition due to trophic disturbance; according to Vogt's theory, primary damage occurs in the vessels, not in the retina as is supposed in the other biotypes. The single biotypes do not transform into one another; each begins in its typical form.

Short Wave Diathermy for Sinusitis.—With a view to correct evaluation of short wave diathermy in the treatment of disease of the nasal sinuses, Hollender repeated the temperature studies of Andreen and Osborne and of Rosenwasser and Bierman. In twenty cases of acute exacerbation of maxillary sinusitis

in which the taking of temperatures through a window was feasible, the following results were obtained: In ten there was an elevation of temperature ranging from 0.6 to 1.5 degrees F., in four there was no gain or loss and in the remaining six there were losses ranging from 0.4 to 1 degree F. The treatments were given with air-spaced electrodes over the affected antrum for periods of fifteen minutes, and in all cases the same apparatus was employed. In a second series of eighteen cases of acute maxillary sinusitis, short wave diathermy (from a 6 meter apparatus) was applied without resort to any other treatment. In a control group orthodox procedures were employed without short wave diathermy, and in a third group short wave treatment was added to accepted routine measures. In the first group, after four days, six of the patients had to be given relief by irrigation, shrinkage and suction. The most unfavorable result was obtained in the group treated by short wave diathermy alone. The most favorable response was obtained in the third group, in which short wave treatment was combined with routine treatment of the sinuses. In a third series of fourteen selected cases of chronic maxillary sinusitis (inflammatory and suppurative but not definitely hyperplastic), in which there had previously been numerous nonsurgical methods of treatment, diathermy was tried over a period of a year to evaluate its effectiveness. Seven of the patients were treated with diathermy alone and seven had the benefit also of intranasal and constitutional remedies. Of the first seven patients only one showed moderate improvement; in the other group of seven, two showed a decided favorable change and only one slight improvement.

Head Injuries and Loss of Hearing.—In defining functional loss of hearing from an industrial angle, Rosenthal assumes that ordinary conversation is carried on within the frequencies 256, 512, 1,024 and 2,048 double vibrations. He bases his deduction on the loss in decibels for these frequencies and calls it functional loss. Of nineteen patients examined after head injuries within a day or two after admission to Gouverneur Hospital or as soon as they became oriented, functional loss of hearing ensued in two. The trauma most often occurred in the basal coil of the cochlea with impairment for perception of the higher frequencies, above 2,048 double vibrations, which does not by itself produce "functional" loss of hearing. Concussion was diagnosed by the neurologist in all nineteen cases, unconsciousness was observed in fifteen, fracture of the skull was shown roentgenographically in five, and the complaint of vertigo (nausea, vomiting and dizziness) was made in six. Loss of hearing for the higher frequencies was diagnosed in nine, in three of which it was bilateral. In the two cases in which there was loss of hearing within the "functional" range, the loss was unilateral.

Excretion of Radioactive Iron.—Hahn and his collaborators studied the iron excreted in the urine, bile and feces of dogs given radioactive iron as ferrous gluconate by vein. In summary they state that there is an initial extra output of iron in the urine and feces for a few days (from three to fifteen) after its injection, and this may total from 2 to 8 per cent of

the injected iron. Following this initial reaction the urinary excretion of radioactive iron drops to traces or even to zero. The feces always contain measurable amounts; in five dogs receiving from 100 to 250 mg. the daily fecal excretion settled down to from 0.05 to 0.4 mg. Blood destruction (acetyl phenylhydrazine) caused a definite increase in radioactive iron eliminated daily in the feces (from 0.1 to 1 mg.). Probably most of this excess of iron came through the biliary tract (bile fistula). The bile under usual conditions contributed but little iron to the intestine (0.01 mg. or less of radioactive iron daily). The body controls its iron stores by absorption or lack of it rather than by the capacity to eliminate it. The evidence is overwhelming that the dog excretes iron with difficulty and in small amounts (even in the plethoric state) by means of the biliary and gastrointestinal tracts.

Industrial Aspects of Chronic Exposure to Benzene.—

Bowditch and Elkins discuss the industrial aspects of continued exposure of workers to benzene (benzol) in several artificial leather plants. Eighty-five workers were examined. There were thirteen serious cases of benzene poisoning, with recovery in only two. The authors made thirty-six urine sulfate ratio determinations and a total of eighty-four atmospheric air analyses. Benzene vapor determinations were made chiefly by the volumetric method developed by Smyth. These tests were made in plants in which relatively good control was maintained. The benzene exposure was as a rule obtained by averaging the results of all vapor determinations made in the given worker's area. These urine samples were taken near the end of the working day, after at least six hours of exposure. The time of day at which the sample is taken is very important, as in every case except that of one worker the ratio of the afternoon sample was more than 20 per cent lower than that of the forenoon sample. The principal two processes involving benzene exposure are the mixing of a nitrocellulose dope, carried out in the compounding room, and the coating of fabric therewith, done in the coating room. There have been eight known recent cases of benzene poisoning terminating fatally in three artificial leather plants. In these plants there were, in all, about sixty workers exposed to benzene vapor in concentrations ranging from 100 to more than 200 parts per million. The compounding room is their chief source of exposure. In three other plants of this type in which the maximal average exposure was judged to be 100 or less parts per million there have been no fatalities. Two plants using benzene rubber cements in the manufacture of crape rubber soles for shoes showed naphtha vapor concentrations of from 300 to 1,300 parts per million. The poisoning cases in these plants, involving women, occurred after relatively short exposures to apparently high concentrations of benzene vapor. In the artificial leather establishments, on the other hand, the exposures have in all cases been longer and, as a rule, less severe. From determinations of atmospheric benzene concentrations in the various shops the data show that the commonly accepted maximal allowable concentration for benzene vapor is 100 parts per million, although Greenburg reported a definite hazard in even lower concentrations. On the other hand, 50 per cent has been proposed as the limiting safe value for the urine sulfate ratio. These two standards are not correlative. A 50 per cent urine sulfate ratio, based on a single sample taken at the end of the working day, would probably correspond to an average benzene vapor concentration of slightly below 75 parts per million. This value has been proposed as the maximal allowable concentration by the Massachusetts Dust and Fume Code Committee and, in the light of their experience,

seems to the authors not unduly restrictive. While they have found that benzene vapor concentrations may readily be kept below 75 parts per million in the majority of industrial processes involving its use, this is not true of all such operations. The fatal outcome to two workers who the authors believe were exposed to average concentrations well below 75 parts per million indicates the possibility of occasional cases of benzene poisoning with even the best of control. Close medical supervision of all benzene workers is thus most important and it is to be hoped that adequate substitute materials will be developed for the more hazardous industrial uses of this excellent solvent.

Clinical Effects of Chronic Exposure to Benzene.—

The clinical effects on eighty-nine individuals exposed to various concentrations of benzene fumes were studied by Hunter, who gathered the material during the last four years. His study included the history, physical examination, routine urine and serologic tests and complete laboratory tests of the blood of each person. In addition, in several instances gastric analyses, cell volume and sedimentation rate determinations were carried out. Furthermore, a diagnostic biopsy of the sternal marrow was performed on certain patients, and in eight of the ten fatal cases a postmortem examination was made. Depending on the degree and duration of exposure, an analysis of the blood indicates that benzene may bring about polycythemia or anemia, leukocytosis or leukopenia, leukemia or leukemoid blood pictures (either lymphatic or myeloid), eosinophilia, megalocytosis or microcytosis, and the presence of immature marrow elements in an otherwise normal blood. The early diagnosis of poisoning depends on an evaluation of the complete blood picture rather than on the existence of a leukopenia. Individual susceptibility is so varied and complex that it seems impossible, at least at present, to explain why one individual is poisoned by the same concentration of fumes—all other extrinsic factors being equal—and another is not. As benzene is a fat solvent, perhaps variations in the quantity of blood lipoids control the amount taken up and held in solution. Thus these substances may play a part in poisoning. If true, this may explain and confirm in part the hypothesis that certain foods act in a protective manner. However that may be, poisoning is certainly a product of three factors: the degree of individual susceptibility, the duration of exposure and the concentration of fumes. Therefore, concentration has a relative but not an absolute importance. Splenomegaly may appear in protracted cases of poisoning. Women are no more susceptible to poisoning than men, and acclimatization to the fumes does not seem to occur. The first signs of poisoning may appear with the onset of an infection, long after exposure has ceased. It is doubtful whether any concentration of benzene greater than zero is safe over a long period.

Chronic Stridor in Infancy.—Bowman and Jackson investigated the causes of stridorous breathing of thirty consecutive infants observed during a period of five years. They found that fourteen of the infants had supraglottic obstruction to inspiration due to deformity or flaccidity of the epiglottis, arytenoids

and/or aryepiglottic folds. Of children who have this difficulty, the epiglottis and arytenoids, forming the upper rim of the larynx, are drawn over the entrance of this organ on inspiration to produce the stridor. Characteristically, in these cases the onset of the noisy breathing was at birth. In five of the cases in which there was noisy breathing, pressure on the trachea was caused by an enlarged thymus gland. Diagnosis in these instances depended a great deal on the observation, on a lateral roentgenogram, of kinking, narrowing and displacement backward of the trachea by a shadow posterior to the manubrium of the sternum. More weight was given to any of these changes when they were observed during full inspiration. Results of endoscopic examinations were negative in all these cases. Before classifying a child in this group, definite improvement in the stridor had to take place forty-eight hours after roentgen treatment. The onset of the symptom in this group was at the second or third month, and the stridor was more marked on expiration. Three of the infants were stridorous because of congenital malformations of the larynx other than those present in the first group. One had weblike ridges in the subglottic area, one a thickening of one of the ventricular bands and one a congenitally small larynx. In each of the eight remaining cases the diagnosis was different: cyst of the thyroglossal duct with pressure on the larynx, tuberculosis of the bronchial lymph nodes, micrognathia, collapse of part of the trachea, congenital heart disease, hypertrophic laryngitis, hypertrophic laryngitis associated with congenital laryngeal stridor; in one case the cause of the altered breathing was not determined. The thirty patients were examined roentgenologically for enlargement of the thymus gland, and twenty-one were found to have some degree of enlargement. Only five infants with enlarged glands were definitely improved after roentgen therapy, while five others were temporarily benefited. Of the nine with thymus glands of normal size there was no change of the symptoms in seven and two were not treated. All these facts reaffirm the difficulty of estimating the importance of this troublesome diagnosis in cases studied because of noisy breathing. Satisfactory study of a child with stridor should include careful x-ray examination of the neck and chest in both planes and an endoscopic examination of the larynx and trachea.

Testis Hormone for Cryptorchidism.—Zelson and Steinitz used the testis hormone in the treatment of twenty cryptorchid boys between $7\frac{1}{2}$ and 13 years of age. Eleven of the twenty children had had previous treatment with gonadotropic substance with no effect. At no time in the past history of the children had the undescended testicle been seen or felt in the scrotum. There was a total of twenty-three undescended testicles; thirteen were palpable and ten were not. Each child was given synthetic testosterone propionate three times a week for from four to ten weeks; the doses varied between 5 and 10 mg. per injection. Four of the boys received a second series of injections of testosterone propionate 5 mg. three times a week in combination with gonadotropic substance (pregnyl) 500 units three times a week for from three to six weeks. The total dosage of gonadotropic substance varied between 4,000 and 8,900 units. None of the children received treatment for longer than ten weeks. Of the eleven boys who had been previously treated with gonadotropic substance two responded to the testosterone treatment: one was affected unilaterally and the other bilaterally; in both the type was pseudo-Froehlich. There was complete descent of testicles in three boys. Of these three, one had unilateral cryptorchidism and two bilateral. Testosterone propionate had a partial effect on some of the other children treated: The testicles of five came down to the lower end of the canal and could be pulled out of the external ring manually but retracted immediately when left alone. The testicles of four which were not palpable at the onset of the treatment became palpable in the canal at the end of treatment. Sixteen boys had enlargement of the penis, eight had enlargement of the scrotum and ten had a definite growth of pubic hair. Only four of the boys showed no effect from the testis hormone. The testicles of five boys became smaller during the course of treatment. In one they became larger. In a four week period one boy grew half an inch in height and another grew 1 inch. Though frequent erections

were reported during the course of treatment, there was no discomfort and no history of masturbation. Of the four boys (having unilateral undescended testicles) who had not responded to the testosterone propionate alone and were given a second course of treatment combined with gonadotropic substance, two responded to this treatment with complete descent. One boy with bilateral cryptorchidism for which testosterone propionate was not effective was subsequently given 10,000 units of gonadotropic substance with resultant complete descent of the testicles. The authors conclude that gonadotropic substance is more effective than testis hormone for the treatment of cryptorchidism. However, when there is no response to gonadotropic substance alone a combination of gonadotropic substance and testis hormone will often cause a response.

Erythema Infectiosum.—The characteristics and general course of an epidemic of forty-three cases of infectious erythema are described by Rector, who believes that from a public health standpoint, because of its contagious nature, it would seem advisable to create a place for erythema infectiosum on the official list of reportable diseases. All the available communications on erythema infectiosum report group infections, although the small size, short duration and relative infrequency of these epidemics point either toward a limited degree of contagiousness or to a lack of general susceptibility to the disease. The epidemics usually attain a peak by the third or fourth week and then subside with equal rapidity, the total duration being but a few months or less. While only 128 cases in the San Francisco epidemic were brought to the attention of the department of health the actual morbidity was much greater, as it is not a reportable condition. Further, many of the initial cases were not recognized, while others were so mild that they were overlooked. Sporadic cases are still occurring in San Francisco. Transmission apparently results from a droplet infection, but the specific agent remains unknown. There is a seasonal incidence, the malady being most frequent in the spring. The age group most commonly affected is from 4 to 12 years. There appears to be a decided sex predilection, girls being more often afflicted in a ratio sometimes as high as 2:1. In one San Francisco school all the cases observed were of girls. The incubation period has been reported to be from five to fourteen days. Among the forty-three cases studied by the author the average period of incubation was from seven to eleven days. Occasionally there is a mild prodrome with slight malaise and sore throat, but in the vast majority of cases the rash, making its initial appearance on the cheeks, is the first and only symptom noted. Within twenty-four to thirty-six hours the eruption develops on the trunk and extremities and spreads toward the periphery, the hands and feet being the last portions of the body to be affected. Whereas the eruption disappears rapidly from the face and trunk, it may last from six to fourteen days on the extremities and an interesting evanescence is often seen, the rash fading for hours or days and then reappearing, usually after slight dermal irritation. Subjective symptoms are practically nil. There is no adenopathy or splenomegaly, and the eruption is not followed by desquamation or pigmentation. Moderate leukopenia with relative lymphocytosis and eosinophilia is usually found. The eosinophils vary from 1 to 16 per cent and average from 4 to 6 per cent. Erythema infectiosum is to be differentiated from the other acute exanthems, from erythema exudatum multiforme and from the various urticarial dermatoses arising from foods, drugs and external irritants. In those occasional cases in which the eruption fails to become confluent on the face, German measles may be suspected until the characteristic features of the disease become evident. In sporadic cases confusion with erythema multiforme or urticaria may occur if the rash is present only on the extremities. Here a negative history, asymptomatic course, absence of pruritus, relatively long duration of the eruptive stage and normal sedimentation rate will all assist in determining the true nature of the condition. Aside from mild symptomatic measures, no treatment is required. As the condition is infectious, the patient should be isolated until the eruption has disappeared permanently. Susceptible contacts should be restricted for two weeks.

Lead Mobilization.—Tompsett and Chalmers studied the effect of high (2.7 Gm. daily) and low (0.13 Gm. daily) calcium diets with and without ammonium chloride in lead poisoning of six lead workers, increased lead absorption in three cases due to lead-contaminated drinking water and one case of lead poisoning due to the latter cause. High calcium diets produced a fall in blood lead, while low calcium diets with and without ammonium chloride produced a rise in blood lead. There was no parallelism between the level of blood lead and lead excretion in the two cases examined. The effect of high and low calcium diets on the distribution of lead between the soft tissues and the skeleton in mice has been studied and it was found that high calcium intakes transfer lead from the soft tissues to the skeleton, while with low intakes the reverse is true.

Blood-Grouping Serums for Emergency Purposes.

With the aid of a small quantity of blood-grouping serums, Challinor and his co-workers selected four human volunteers of group II and four of group III. The object was to find out which of them could provide the most active serums for standard typing purposes in emergencies. By setting up a series of increasing dilutions of each individual's serum, to which was added a suspension of erythrocytes, it was possible to determine which of the serums produced clumping in the highest dilution and to ascertain the character and nature of the clumping produced. The results showed that the serum possessing the highest end titer of agglutinins was not necessarily the serum of choice for typing purposes, since the qualitative character of the reaction—for example the size and appearance of the clumps as seen by the naked eye—was a better criterion of the value of serums for typing work than the end titer at which the reaction occurred. It is desirable to add a preservative to typing serum, and phenol was used in order to avoid excessive dilution of the serum. The most suitable two donors from each group were chosen and from half to three fourths of a pint (240 to 360 cc.) of blood was withdrawn from each donor into sterile pint bottles and allowed to stand overnight in the ice box. During this preliminary storage the absorption of any "cold" agglutinins takes place. The separated serum was transferred by means of sterile pipets into sterile 100 cc. bottles. In order to maintain sterility, phenol (5 per cent aqueous solution) was then added to the serum so that the phenol concentration was 0.5 per cent. For distribution purposes the phenolized serum was transferred in 1 cc. quantities to sterile vials fitted with rubber bungs, which were afterward waxed. As an alternative method for the preservation of typing serums the authors used the method employed by Craigie (1931) and Craigie and Tulloch (1931). This is

the preservation of serums by desiccation in vacuo from the frozen state. The only disadvantage of using dried serum is that larger quantities are required than of the fluid serum; but this disadvantage is offset by the fact that desiccated serum is easily distributed and handled, and, in any case, the actual amount of dried serum needed for a typing test is exceedingly small.

Pathogenic Staphylococci in Nose and on Skin.—Gillespie and his associates point out that during an investigation of an outbreak of septic infections in operative wounds Devenish and Miles found that three of four surgeons tested were nasal carriers of *Staphylococcus aureus*. One of these three was a persistent cutaneous carrier of a strain of *Staphylococcus aureus* identical with the nasal strain. Since there appears to be no record of any survey of the incidence of staphylococci both in the nose and on the skin in which the cocci were identified as potentially pathogenic, Gillespie and his associates determined the nasal and cutaneous carrier rates in medical students. Two surveys were made. In the first, swabs were made of 159 students. Of the 159 nasal swabs, sixty-nine were positive, a nasal carrier rate of 43.4 per cent. There were thirty-one (19.5 per cent) cutaneous carriers (right or left wrists or both). The total population may be conveniently divided into four groups: group A are nasal carriers, B double carriers, C cutaneous carriers and D noncarriers. Approximately 50 per cent are carriers of *Staphylococcus pyogenes*, which in 30 per cent occurs only in the nose, in 13 per cent in the nose and on the skin—double carriers—and in only 7 per cent on the skin alone. There was no relation between the carrier rates and the length of the students' sojourn in the hospital, nor was there any association with the age or sex of the student. Regarding the nasal carrier state and the history of chronic nasal disease, the authors say that of the population sampled thirty-nine gave a history of chronic nasal disease in the form of discharge, chronic catarrh or sinusitis; twenty-five of these were nasal carriers of *Staphylococcus pyogenes*. The percentage difference between the incidence of nasal disease in nasal carriers and in the remainder of the students is 20.7 ± 6.9 , suggesting that there is an association between the two conditions. About the relationship of nasal and cutaneous carrier states and infections of the skin, the authors say that several of the persons tested had a history of superficial cutaneous infections, such as boils or pustules. The positive carriers showed a slightly higher percentage of cutaneous infections, but the difference is not statistically significant. The second survey, made several months later, was designed to test the constancy of the nasal and skin carrier states and their association and to compare the incidence of *Staphylococcus pyogenes* on the skin, determined by superficial swabbing, with that in the deeper parts of the skin. Ten students were selected at random from each of the four groups A, B, C and D and swabs were made as before. They also washed up as for an operation. After putting on dry sterile rubber gloves each student was exposed to a humid atmosphere. Sweating was induced by the immersion of the gloved hands in a hot water bath. As soon as perspiration appeared on the forehead and inside the gloves, 0.5 cc. of broth was pipetted into each glove and well massaged into the hands. The gloves were then peeled off and their inside surfaces pressed on to Fildes's agar plates, which were incubated and examined for *Staphylococcus pyogenes*. This survey revealed that some of the students remained in their original groups, while in others changes occurred. Repeated swabbing of the nose revealed a relative constancy of the nasal carrier state. The glove test distinguishes those who carry *Staphylococcus pyogenes* superficially enough for its complete removal by surgical scrubbing from those in whose skin

the infection is deep. There were fifteen superficial cutaneous carriers among the forty students tested, but of these only five were deep carriers by the glove test. Moreover, all five deep carriers were in the double carrier group. In all five the glove strains were identical with the superficial skin strains, and in four of the five the nasal strain belonged to the same serologic type. It appears, therefore, that the persistent cutaneous carrier state in a surgeon tested by Devnish and Miles was not an isolated phenomenon but one which is relatively common.

Vitamins D₂ and D₃ in Rickets.—Morris and Stevenson show that the clinical investigations so far recorded are by no means unanimous as to the relative potencies of vitamins D₂ and D₃ in the treatment of rickets in the infant. In the present study they attempt to compare the potency of crystalline vitamins D₂ and D₃. The real difficulty of the assay was to make certain that the only variable was the vitamin. The diet was a milk mixture consisting of two-thirds milk and one-third water, with sugar and oat flour in amounts suitable for the age of each patient. The infants were kept together on the same side of the ward out of direct sunlight. As far as possible, infants of the same age were used for comparison. Every patient was kept in the ward for at least three weeks before the vitamin was administered, to ensure as far as possible that the rickets had not begun to heal before specific antirachitic therapy was instituted. It was felt that any differences in the effects of vitamins D₂ and D₃ would be best detected if the dosage was on the low side. Since ordinarily a patient with rickets would almost certainly be receiving some antirachitic factor either in the diet or by natural ultraviolet irradiation, it was felt that a dose of 2,000 international units a day was on the low side for curative purposes. This amount was given to each patient, irrespective of age and weight. Accordingly the dose varied with each pair from 140 to 286 international units per kilogram of body weight daily. The authors studied the course of healing in twelve infants and children with active rickets, six of whom were given vitamin D₂ and six vitamin D₃. Serial x-ray studies were made of the wrists, and the plasma phosphatase was estimated. The results revealed no significant difference between the therapeutic effects of these two vitamins on rachitic infants and children.

- *Endocrine Gland in Wall of Renal Arterioles. N. Goormaghtigh.—p. 1541.
Malaria Therapy: Clinical and Social Results in Dementia Paralytica: C'tn. R. Bernard.—p. 1550.

Endocrine Gland in Wall of Renal Arterioles.—Goormaghtigh believes that he has traced a previously unknown endocrine gland to its site in the wall of the arterioles of the kidneys. This gland, according to the author, consists of muscle cells devoid of muscle fibrils within the media of the renal arterioles at the point where the capillary ramifications constitute a glomerular tuft and the fibrilless cells aid in forming a juxtaglomerular structure with regulating effect on glomerular circulation. In his morphologic studies on animals the author found, especially in rabbits, that a variable number of cells of the juxtaglomerular organs, clearly resembling chromophil cells of the anterior lobe of the hypophysis, contained acidophil and basophil secretory granules. In his experimental studies of the fibrilless cells in dogs and rabbits he observed that renal ischemia provoked hypertrophy and the multiplication of certain cells normally devoid of fibrils in the media of the renal arterioles, causing the transformation of muscle cells with fibrils into cells without fibrils, these cells becoming granular in rabbits and occasionally so in dogs. He also noted that, if ischemia persisted for several months, numerous fibrilless substances in the arteries of the kidneys of dogs likewise became granular and acquired endocrine characteristics. The author feels justified in concluding that, since renal ischemia stimulates almost exclusively the cells of the media of the renal arterioles, the source of the hypertensive hormone must be sought in these cells. He also thinks that hypertension secondary to nephritis, the etiology of which is still obscure, may be attributed to the stimulation of the fibrilless cells of the juxtaglomerular organs. Definite proof of this new gland awaits hormonal isolation from the media of renal arterioles, though, as the author points out, the endocrine function of the islands of Langerhans was discovered twenty-five years before the isolation of insulin.

*Insulin Therapy in Diabetes. H. Chabanier and C. Lobo-Onell.—p. 1454.
Hypertonia of Levator Muscles of Eyelids: Physiopathologic Mechanism of Graefe's Sign. A. Kreindler.—p. 1457.

Insulin Therapy in Diabetes.—Chabanier and Lobo-Onell stress the normalization of glycemia in diabetic persons, not merely the reduction of glycosuria, as the significant thing in the management of diabetes. Fortified by seventeen years' use of a technic that employs a moderate carbohydrate regimen in conjunction with relatively large doses of insulin (800 units within fourteen hours; from 240 to 400 units within twenty-four hours), the authors challenge the therapeutic practice of carbohydrate and insulinizing the patient with small doses (10, 20, 30 units) into a state of sugar free urine, with little or no regard to hyperglycemia. Their statements are based on the superior results claimed for their method in protecting diabetic persons against postoperative sequels when surgery had to be resorted to, against infectious diseases such as anthrax and gangrene, against supervening complications, organic and neurosensory, and against the evolution of diabetes. For example, no cases of postoperative acetonemia or death occurred in 111 diabetic persons primarily treated for glycemia, whereas, in twenty-one cases treated for glycosuria, serious keto-acidosis and four deaths resulted after surgical intervention. No infectious aggravation of anthrax was noted among their own patients; furuncles observed in eleven of their patients did not proliferate, whereas, of fifteen patients under glycosuria control, eleven developed anthrax, three died in coma and three died from septicemia. Gangrenous infection, though frequently observed in their own patients, did not evolve and healed normally after incision, whereas eleven deaths occurred among twenty-seven persons treated for glycosuria, keto-acidosis, coma and septicemia. Only thirteen instances of arthritic gangrene were noted by the authors among their own patients within thirteen years, whereas numerous cases of organic and neurosensory complications were observed in persons treated primarily for glycosuria.

According to the authors, insulin not merely constitutes a substitutive medication but is capable of curative effects both in adults and in children in the sense that improvement is achieved while glycemia is maintained within normal limits on an uninterrupted carbohydrate regimen and the doses of insulin are reduced. In one case a daily dose of 200 units could be reduced to from 16 to 18 units without affecting the glycemic level. They believe that while their method is no guaranty against diabetic gangrene it confers maximal prophylaxis.

*Examination of Thrombocytes in Unstained Dark Field Preparation. A. Fonio.—p. 952.

Importance of Technic in Heliotherapy. A. Rollier.—p. 958.

Thrombocytes in Dark Field Preparation.—According to Fonio the dark field preparation permits the visualization and the photomicrographic reproduction of the individual thrombocyte in its various evolutive phases. It reveals that the thrombocyte is a cell which consists of cytoplasm and granules, which presumably have the role of the nucleus. The granules are highly luminous formations; their number differs and their distribution in the cytoplasm is irregular particularly in the irritative forms, whereas in the quiescent forms they are centrally located, like a nucleus. The behavior of the cytoplasm varies with the evolutive form of the cell. Shortly after centrifugation the thrombocyte has a roundish or oval form with short pseudopodia, which gradually increase in length. There are several types of pseudopodia: (1) wide and rigid ones and (2) narrow and long ones with screw-like movements. The latter pseudopodia, which might be designated as "haptopodia," may become quite long and may, apparently induced by chemotactic stimuli, reach out for other thrombocytes or other particles. Some pseudopodia branch out into secondary pseudopodia. The author describes the changes in the thrombocytes before, during and after the precipitation of fibrin and what happens when several thrombocytes come together, and he analyzes the biologic significance of the cytoplasm and of the granules. He shows reproductions of a number of photomicrographs of thrombocytes.

*Sterilization of Diphtheria Carriers. V. Lanza and E. Di Fulvio.—p. 1955.

Spastic Paraplegia of Little's Type. E. Rizzatti.—p. 1897.

Sterilization of Diphtheria Carriers.—Lanza and Di Fulvio used daily local applications of pure anatoxin on the nasal, pharyngeal, laryngeal or laryngopharyngeal mucosae of a group of eighty-four carriers harboring diphtheria bacilli. The group included convalescents and healthy carriers. In resistant cases the local treatment was given in association with hypodermic injections of increasing doses (0.5, 1, 1.5 and 2 cc.) of anatoxin. The injections were administered at intervals of five or six days up to a total number of two or four. Control of the bacilli was verified by cultural researches, which were carried on at intervals of five days. Sterilization was obtained in seventy cases in from five to thirteen days and in fourteen cases in from fourteen to twenty-five days. The treatment is simple and harmless.

Examination of Heart and Differential Diagnosis by Means of Electrocardiogram and Kymogram. H. Reindell.—p. 1423.

Lactating Ability and Its Duration.—According to Reuss the diagnosis "deficient lactating ability" is hastily made in most cases. Women with hereditary deficiency of lactation are in the minority and a number of women producing a small amount of milk at the start of breast feeding may be brought to provide more than half or even all the child's requirement by systematic pumping, which still is the best means of rendering lactation more active. The cooperation of the patient is essential in this process. Forceps delivery, severe hemorrhages,

eclampsia and particularly puerperal fever may considerably influence lactation during the puerperal period. It is not right to speak of a deficient lactating ability in such cases, and the temporarily retarded activity of the mammary glands can be remedied as soon as the patient gets well and appropriate measures have been taken. "Initial hypogalactia," the term used by the author, is particularly frequent in mothers of prematurely born children. Laziness or weakness of the infant in sucking may sometimes convey the impression of hypogalactia of the mother. It is advisable in such cases to evacuate the mammary glands by mechanical means and feed the breast milk to the child from a bottle. The lactating ability of mothers can be maintained and only a serious disease such as mastitis can impair the activity of the mammary glands. The author recommends the creation of more ample facilities for admitting the mothers with the infants to clinics and hospitals. Mothers and students would both benefit thereby. Institution of mother's milk bureaus on a larger scale is likewise recommended.

Diameter of Erythrocytes.—Schalm reviews and evaluates the different methods that have been recommended for the measurement of the erythrocytic diameter. Direct measurement is accurate but time consuming. The method in which the cells are projected, drawn and measured afterward probably yields the most reliable results. The measuring of 200 cells is generally sufficient. Only in cases of considerable anisocytosis is it advisable to measure a larger number of cells. For clinical use the diffraction method is usually employed. Practice has taught that the deviations from the norm are reliably rendered by this method. Schalm also discusses the clinical value of the determination of the erythrocyte diameter. He admits that there are physiologic differences, but as a rule the normal values do not differ more than 0.4 micron. A considerable deviation of the size of the red blood cells indicates the existence of a pathologic condition, but a normal diameter does not exclude such a process. In pernicious anemia the enlarged diameter is a typical symptom, which appears early in the development of the disease. In fully developed cases the diameter is enlarged by 1 micron or more. Since the introduction of the liver treatment of pernicious anemia, considerable attention has been given to changes in the erythrocyte diameter. It was observed that the diameter decreased after this treatment. If the diameter increases during the maintenance treatment, it must be concluded that the treatment is insufficient. In sprue and similar conditions the mean diameter of the erythrocytes is often found to be distinctly enlarged. Normal diameters have been found in true cases of sprue. Moreover, the changes in the diameter are not a reliable indicator of improvement or relapse in sprue. After successful treatment the cells may remain enlarged. Changes in the mean diameter have been observed in the anemias that are thought to be due to defective formation of the antianemic principle, for instance in the anemia that is caused by dietary deficiency or in the anemia after gastrectomy. Macrocytosis has been observed also in the so-called pernicious anemia of pregnancy and in the anemias due to infestation with helminths. In the so-called secondary hypochromic anemias, the erythrocyte diameter is often smaller than normal. In hemolytic jaundice the microcytosis is usually quite pronounced, the reduction of the erythrocyte diameter amounting to about 1 micron. Although microcytosis may be of value in the diagnosis of hemolytic jaundice, its absence does not justify the rejection of this diagnosis. In neurologic disorders the determination of the erythrocyte diameter may help to decide whether such a disorder is due to pernicious anemia or not. Finally the author discusses the erythrocyte diameter in leukemia, in malaria, in renal and circulatory diseases and in endocrine disturbances. In the concluding summary he stresses, among other factors that it is wise not to attach too much value to small changes in the diameter.

Surgical Treatment of Pericarditis.—According to Westermann, surgical treatment of pericarditis has increased in recent years, not because of the more frequent occurrence, especially of its callous or contracting forms, but rather because this syndrome has become better known. Two circumstances are influential in the appearance of severe functional disturbances of the heart: (1) the extension of the inflammation of the pericardium to the mediastinum with adhesions on the posterior wall of the sternum and on the ribs (accretio cordis) and (2) the shrinkage of a concentric callosity with compression of the heart and contraction at the site of entry of the large vessels (concretio pericardii). The author points out that the technic for the resection of the pericardium was developed chiefly by Schmieden, who in thirty-four cases had a total mortality of 44.1 per cent and 55.9 per cent of cures or improvements. The author thinks that 56 per cent of cures or improvements must be regarded as a considerable advance, particularly in the treatment of the callous and contracting terminal forms of pericarditis. He believes that the mortality could be reduced still further if the patients were not all in an advanced stage of the disease at the time of the operation but were subjected to treatment during the earlier stages. Since there is little prospect of further improvement in the already highly developed surgical technic, the author thinks that a betterment of the surgical results can be expected only from a better selection of the cases. At the author's clinic not every patient with pericarditis is subjected to an operation, but only those who require it and who may be expected to tolerate it. Pericarditis without a tendency to shrinkage and contraction may be cured without a surgical operation. However, in the callous and shrinking forms in which the inflow of the blood is impaired, an early operation provides the best prospects of permanent success. Such an early operation presupposes an early diagnosis, which will be possible only if physicians recognize the symptoms. The operation is contra-indicated only during the exudative stage of pericarditis, because when performed during this stage it is frequently followed by prolonged, occasionally tuberculous, fistulous suppurations. The only operation that promises success is not the precordial cardiomyolysis but rather a partial resection from the shrunken pericardium.

Occupational Injuries of Heart. K. Blumberger.—p. 1260.

Familial Leukemia.—Decastello cites a number of investigators who observed and discussed familial leukemia, directing especial attention to a report by J. Weiss, to which his attention was drawn in connection with a case of leukemia that came under his observation. His patient, a woman aged 48, proved to be a member of the family in which Weiss had discovered five cases of lymphocytic anemia. After describing the clinical history of this woman the author shows a diagram of the genealogical tree of the family under consideration. This diagram indicates that, of five siblings, three, a sister and two brothers, had chronic lymphocytic leukemia, that the aforementioned sister had seven children, two of whom developed the same disorder, and that a daughter of one of the two leukemic brothers likewise developed lymphocytic leukemia. The latter patient was the woman who came under Decastello's observation, whereas the other five cases had been observed by Weiss. Decastello briefly reviews the histories of the cases presented by Weiss and says that, although only one of the six cases of familial lymphocytic leukemia was verified by necropsy, the diagnosis can

be regarded as definitely established in all except one of the cases. In this case the disorder took an aleukemic and subacute course and it is possible that the disorder in question was a lymphosarcomatosis. In only one instance did the leukemia appear during youth and in this case the course was extremely slow (fourteen years). In all others it developed when the patients were between 40 and 50 years of age and terminated in from five months to four years. The author concludes that the occurrence of these six cases of leukemia in two generations of the same family indicates that a hereditary factor may occasionally be a factor in leukemia.

Effect of Single Roentgen Doses on Bone Marrow of White Mouse. H. Langendorff and W. Papperitz.—p. 624.

Fractional Roentgen Therapy in Advanced Uterocervical Carcinoma.—According to Kirchhoff, ureteral complications in uterocervical carcinomas are frequently observed roentgenologically and constitute the most common cause of the fatal termination of this disease through the stages of oliguria, anuria and uremia. While radium therapy shows a greater mortality debit than roentgen irradiation, the latter is, says the author, by no means so innocent of ureteral strangulation as assumed. He records the various measures proposed to destroy tumor formations and thus to relieve and release ureteral constriction and reports the successful application of simple fractional irradiation (modified Coutard method) in five of seven cases (one recidivation with bilateral hydronephrosis) of cervical carcinoma. The age level of the patients was between 31 and 68 years. Fractional therapy, employed by the author in hundreds of cases, calls for a single skin dose of 400 surface roentgens. The individual field receives from eight to ten of such applications within forty-eight hours, equivalent to a total of from 3,200 to 4,000 roentgens. Areas thus treated are the abdomen, back, sides and several perineal and vulval fields. The author regards as imperative, in cases of cervical carcinoma, the systematic examination of the urogenital tract by means of roentgen rays in addition to cystoscopic study and residual nitrogen determination. Bilateral constrictions require extreme care in roentgen ray management to prevent ureteral strangulation. In unilateral constrictions, the healthy kidney may be presumed to assume the function of the diseased. However, roentgen irradiation may evolve reflex constriction of the healthy kidney, for which ureteral catheterization is mandatory. The author thinks that in cases in which the parenchyma of the organ has been seriously impaired and hydronephrosis has existed for a long time, no reconstruction can be counted on. Fractional roentgen therapy with high dosage, involving even the possibility of sequels, is indicated whenever every other therapeutic management is contraindicated.

*Effect of Nicotine on Potassium and Calcium Blood Content and on Potassium/Calcium Quotient. P. Scheer.—p. 314.

Effect of Nicotine on Potassium and Calcium Blood Levels.—Scheer investigates the effects of nicotine on the potassium and calcium levels in man (forty) and rabbits (ten). The forty persons chosen consisted, for the most part, of healthy men, women, younger persons, a few patients afflicted with gastritis and ventricular and duodenal ulcers and included smokers and nonsmokers. The investigation excluded persons in whom an endocrine disease was indicated. Tests on man were made by extracting venous blood before food ingestion

followed by the inhalation of two or three cigarettes of from 1 to 1.1 Gm., all of the same brand. The second blood sample was taken at the height of nicotine intoxication evidenced by sweat, nausea, vomiting, tremors and so on. Further blood samples were taken at intervals of fifteen, thirty, forty-five and sixty minutes, partly also after ninety, 120 and 180 minutes, throughout under conditions of food abstention. The author indicates the methods employed to determine potassium and calcium levels and the procedure adopted for the determination of these levels in the rabbits. He found that the average potassium level of 21.49 mg. per hundred cubic centimeters and the average calcium level of 11.8 mg. corresponded with the levels recorded in the literature. The evaluation of the results of the nicotine reaction necessitated the formation of three groups. The first group (70 per cent) showed an increase of the calcium level, varying individually between 16.8 mg. per hundred cubic centimeters and a percentage that did not exceed the average by more than 1 and 1.5. Return to normal levels occurred on an average after forty-five minutes and at the latest after sixty minutes; a few cases, however, falling below the potassium level. On the other hand, the potassium level decreased at various intervals, occasionally after forty-five minutes, and was characterized by further irregularities. The fall of the potassium/calcium quotient was indicative of a sympathicotonic reaction. In the second group (9 per cent) the potassium level showed an increase and the calcium level a decrease, a process evolving within forty-five to sixty minutes, at which time the calcium level attained its initial stage while the potassium level continued to rise in most cases, so that increased levels could be observed after from ninety to 120 minutes. The potassium/calcium quotient was indicative of a vagotonic reaction. In the third group (22 per cent) a regular increase of potassium and calcium levels, occurring within the same time as that of the other two groups, was observed. The author discovered that the cases of gastritis and ventricular and duodenal ulcers fell within this group and that the nicotine elicited increased potassium and calcium responses, considerably so in the case of potassium. The potassium/calcium quotient in this third group was enhanced. No essential differences were noted in the reactions of youths, adults, smokers and nonsmokers. Toxic phenomena differed individually or in degree. The toxic effects in the rabbits, especially after intravenous injections, consisted of tachycardia, tachypnea, salivation, occasional tonic-clonic spasms and a noticeable loss of weight at the end of the probation period. Subcutaneous injections of 1 mg. per kilogram of nicotine solution administered daily for four weeks induced an increase in the potassium and calcium levels of the serum. Increased intoxication induced by intravenous injections of from 0.5 to 1 mg. per kilogram of nicotine tartrate for six days could heighten the levels only to a small degree. It was found that three days after the injections were terminated the potassium and calcium serum levels sank and that after about three weeks the initial levels were restored.

Eye Complications in Scarlet Fever.—Scalongne reports that a child aged 18 months had a serious conjunctivitis from scarlet fever. The conjunctivitis did not yield to the customary treatment but was followed by keratitis, phlegmon of the upper lid and retrobulbar abscess, which lesions healed with a large residual macula cornea. After that the other eye became involved. There were conjunctivitis, phlegmon of the upper lid, panophthalmia and atrophica bulbi. Rhinitis developed and there was a discharge from the nose and both eyes. Bacteriologic examination of the conjunctival secretion revealed *Streptococcus haemolyticus*. The child died several months later during an

attack of high fever, but permission for a necropsy was refused. At first the author was not certain that the ocular complications were caused by scarlet fever, but observations in other cases made this seem probable. A second child was hospitalized with the typical symptoms of scarlatina. On the fourth day rhinitis and conjunctivitis developed. This was followed by keratitis, phlegmon of the upper lid and atrophica bulbi. On the other eye there developed, almost simultaneously, conjunctivitis and keratitis. The resulting vision permitted only reception of light. A third child with scarlatina had conjunctivitis at the time of admittance and soon keratitis and phlegmon of the upper lid developed. After this eye had almost healed, a phlegmon developed on the upper lid of the other eye, followed by eversion of the lids, necrosis of the conjunctiva and probably panophthalmia. At the postmortem examination purulent meningitis was discovered. In the fourth case purulent conjunctivitis developed followed by phlegmon of the upper lid and keratomalacia, leaving a macula on the lower half of the cornea but good vision. Simultaneously the other eye showed a phlegmon of the upper lid and keratoconjunctivitis. After healing, a small macula remained. The author thinks that the nasolacrimal duct cannot be considered the route of infection, although such cases have been reported in the literature; nor can secondary infection be clearly demonstrated as a cause. He thinks that there is a possibility that hypovitaminosis played a part in the development of the lesions. Although there were some indications of hypovitaminosis, valid proof of its causal significance could not be furnished.

Vitamin A and Respiratory Infections.—Uddström says that the significance of vitamin A for the resistance against infections and for the favorable modification of existing infections is generally accepted. However, objections have been made against the use of the term "anti-infectious vitamin." Objectors to this term have pointed out that vitamin A is only one of the many constituents of a well balanced diet which insures an adequate defense of the organism against infections. The author thinks that a diet which is so deficient in vitamin A that it results in symptoms of vitamin A deficiency is insufficient also in other respects. In this report he gives his attention to whether the subclinical or latent forms of vitamin A deficiency are likewise accompanied by an increased susceptibility to infections and whether the administration of vitamin A is advantageous in the absence of signs of vitamin A deficiency. He reports investigations on school children in a Swedish industrial region with a high percentage of unemployment. One half of the children for four months were given daily, except Sundays and holidays, 8,000 international units of vitamin A. The suggestive factor was eliminated by giving to the other children an indifferent substance of similar appearance. The medication with vitamin A exerted no influence on the growth in height or on the increase in weight; moreover, as regards infections of the respiratory passages it had no influence on the morbidity. On the basis of reports in the literature and of his own investigations the author concludes that the present knowledge about vitamin A does not justify the maintenance of the term "anti-infectious vitamin," at least if it is to designate an action that is entirely different from that of other nutritive substances. It may be regarded as definitely established that in cases in which there exists a great deficiency in vitamin A the resistance against infections of the respiratory tract is impaired. However, it cannot be asserted that slight degrees of vitamin A deficiency impair the resistance against respiratory infections. An oversupply of vitamin A is of no special advantage with regard to susceptibility for infections of the air passages. A favorable action of medication with vitamin A on the incidence, duration or severity of respiratory infections justifies the conclusion that a considerable vitamin A deficiency existed.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE

DEPARTMENT, JULY-DECEMBER 1939

Titles have been listed or Abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1930. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "SS," Student Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2520.

A

A. T. 10: See Dihydrotylchosterol

syphilis; Vincent's angina diagnosed as, 1594
syphilis; Wassermann test, failure to make, 1594
tonsillectomy; injury to recurrent laryngeal nerves, 1059
tonsillectomy; loss of voice attributed to, 1059
trench mouth; mistakenly diagnosed as syphilis, 1594
Vincent's angina; mistakenly diagnosed as syphilis, 1594
vocal cords; tonsillectomy in relation to loss of voice, 1059
voice; loss of attributed to tonsillectomy, 1059
Volkman's paralysis; cast as cause of, 1515
MEDICAL PRACTICE ACTS: chiropractic; as practice of medicine, 711, 1670
chiropractic; diagnosis by, 1670
chiropractic; possession of chiropractic license need not be negated, 711
corporations; legislature, not courts, must legalize corporate practice, 621
corporations; medical care supplied on prepayment plan, 1515
corporations; nonprofit status, effect of, 621
corporations; physicians selected by as independent contractors, 621
corporations; right to practice medicine, 88, 621
corporations; solicitation of contracts, 621
diagnosis; chiropractic, 1670
"doctor"; use of title as practice of medicine, 1670
drugless healers; sufficiency of evidence, 1857
electrolysis; as practice of medicine, 1764
evidence; "holding self out" as practitioner of medicine, 1670
examining boards; revocation proceedings; professional knowledge of board members as evidence, 1337
examining boards; rules required examination of all foreign licensees; validity, 1668
exemptions; osteopaths; effect of, 447
foreign licensees; validity of examination requirement, 1668
licensees; examination required of all foreign licensees; validity of rule, 1668
licensees; reciprocity; burden of proving qualifications on applicant, 1668
licensees; reciprocity; foreign licensees entitled to endorsement, when, 1668
licensees; revocation; addict, narcotic; prescribing for, 1837
licensees; revocation; crimes; moral turpitude, 1837
licensees; revocation; either court or board may revoke license, when, 1764
licensees; revocation; expert testimony, when necessary, 1837
licensees; revocation; Harrison Narcotic Act; violation of as involving moral turpitude, 1837
licensees; revocation; "moral turpitude"; conviction of crime involving, 1837
licensees; revocation; unprofessional or dishonorable conduct; prescribing for narcotic addict, 1837
licensees; revocation; violation of state narcotic act, 1764
municipalities; applicability of act to, 534
osteopathy; enactment of separate act; effect of, 447
MEDICAL SERVICES: indigents; county's liability for medical services, 1910
municipalities; group health plan for employees; deductions from pay; validity, 534
municipalities; group health plan for employees; validity of exemptions, 534
municipalities; right to provide health service for employees, 534
MOTOR VEHICLES: drunken operator; "under the influence of liquor" construed, 358
MUNICIPALITIES: See Medical Services
NARCOTICS: cannabis; judicial notice that marihuana is cannabis, 1669
marihuana; as belonging to cannabis family; judicial notice, 1669
prescriptions; issuance to feckless person, 533
revocation of physician's license; either court or board may revoke, 1764
NATUROPATHY: drugs; right to use, 2087
narcotics; right to use, 2087
phyiotherapy; narcotics as embraced by, 2087
OPTOMETRY: co-operative arrangement between optician and physician, 1909

OPTOMETRY—Continued

corporate employer's liability for optometrist's negligence, 2180
corporations; right to practice, 88
disease of eye; duty of optometrist to detect, 2180
doctors of medicine; employment by laymen to make examinations, 88, 1909
enforcement; injunctions to restrain violations, 88
professional status of optometry, 88
property rights; license to practice as constituting, 88
OSTEOMYELITIS: trauma and arthritis in relation to, 353
OSTEOPATHY: amendments to osteopathic act; omission of specific prohibition on use of drugs and surgery; effect of, 447
drugs; right of practitioner to use, 447
schools; delegation of legislative authority, 447
scope of; "as taught in osteopathic colleges" construed, 447
scope of; statute construed as of date of enactment, 447
surgery; right of practitioner to practice, 447
PARALYSIS: See Hemiplegia; Malpractice
PATERNITY: blood grouping tests as evidence, 970
PHARMACISTS: prescriptions; misrepresentation as to ingredients of compounded drug, 3343
prescriptions; substitution in compounding, 3343
PILES: See Hemorrhoids
PNEUMOCONIOSIS: silicosis; employer's duty to provide safe place of work, 1908
PNEUMONIA: trauma in relation to, 884
POISONING: lead; tetra-ethyl gasoline the cause of, 257
lead; workmen's compensation in relation to, 257
PREGNANCY: Friedmann test; failure to make; malpractice, 1762
PRIVILEGED COMMUNICATIONS: assistant to physician within rule, 2180
hospital records, 1670
wife of physician within rule, when, 2180
ROENTGENOGRAMS: See Evidence; Malpractice
RUPTURE: See Hernia
SCHOOLS: chiropractic; delegation of legislative authority to, 711
exclusion of unvaccinated pupil; father's liability for failure to send child to school, 1160
osteopathic; delegation of legislative authority to, 447
vaccination; exclusion of unvaccinated pupil, 1160
SILICOSIS: See Pneumoconiosis
SMALLPOX: See Vaccination
STRAIN (Over-Exertion): hemiplegia in relation to, 1670
hemorrhoids in relation to, 1596
hernia in relation to, 1910
thrombosis, cerebral, in relation to, 1670
thrombosis, coronary, in relation to, 1251
SULPHURIC ACID: cancer of tongue in relation to, 1440
SYPHILIS: Vincent's angina diagnosed as, 1594
TARIFF ACT: contraceptive literature; importation of; confiscation, 1253
TAXES: estate; antivivisection society as engaged in charitable activities, 1595
legislative activities; charitable status of organization as affected by, 1595
THROMBOSIS: cerebral; strain (over-exertion) in relation to, 1670
coronary; strain (over-exertion) and worry in relation to, 1251
coronary; workmen's compensation in relation to, 1251
TRAUMA: appendicitis; back injury in relation to, 1594
arthritis in relation to, 358
bladder; dysfunction in relation to, 1669
insanity in relation to, 970
pneumonia in relation to, 884
TRICHINOSIS: packer of meats; joint liability with retailer, 1596
VACCINATION: schools; exclusion of unvaccinated pupil; father's liability for failure to send child to school, 1160
VINCENT'S ANGINA: syphilis mistaken for, 1594
VIVISECTION: antivivisection society as engaged in charitable activities, 1595
VOLKMAN'S PARALYSIS: See Malpractice

SUBJECT INDEX

2518

VISSCHER-Bowman Test: See Pregnancy diagnosis

VITAL CAPACITY, systolic murmur and French horn playing, 83

VITAL RED, Brilliant: See Epilepsy treatment

VITAL STATISTICS: See also Population

birth rate, human reproductive patterns, 1645-E

birth rate (illegitimate) in U. S., 1329-E

birth rate, lower, Argentina, 611

birth rate recovery by Australia, 2074

census in 1940, U. S., 2155-OS

centenarians (over 1,000) in Rumania, 1504

death certification during war, England, 1821

death rates ("crude") in large cities, U. S., 2332

death rates higher among males, 1454-ab

Mortality: See also Abortion; Erysipelas; Infants; Maternal mortality, etc.

mortality, 9 leading causes, 1424

mortality trends in Illinois since 1935, 864

of England, 1746

of Germany, 1425

Physicians' Handbook, 2422-E

VITAMIN Treatment: See Fractures

VITAMINS, cellular respiration, 417-E

concentrations, restrict sale, N. H., 1743

Conferences on Therapy discuss, *297

deficiency in Spanish civil war, 160

deficiency, nail changes as sign, [Low] 457

-ab

fortification of foods, (Council discusses) 681; (Cooperative Committee recommendations) *593; 598-E

in mutton bird oil, 871

mixtures, Cooperative Committee report, *593; 598-E

VITAMINS A: See also Carotene

Bitot's spots in Ceylon, [Nichols] 1176-ab

Cooperative Committee recommendations, *590; 598-E

dark adaptation and, [Manville] 540-ab; [Thomson] 1173-ab; [Patek] 1600-ab; 1660; [Feldman] 1992-ab

deficiency, [von Drigalski] 1264-ab

deficiency and renal calculi, [Higgins] *1462; [Long] 1772-ab

deficiency cause of keratoconus, [Mutch] 721

-ab

deficiency effect on blood, [Abbott] 623-ab

effect on adrenal insufficiency, [Veslaw] 2190

-ab

effect on wound healing, 2254

in blood of normal adults; effect of depletion diets; biophotometer readings, [Steininger & others] *2381

in liver in tuberculosis, [Crimm] 1255-ab

ointment (vulnivorin) for ocular disorders, [de Grósz] 2452-ab

resistance to respiratory infections and, [Uddströmer] 2460-ab

VITAMINS B COMPLEX, anti-gray hair factor, [various authors] 2110-ab

Cooperative Committee recommendations, *590; 598-E

deficiency induced by rapid carbohydrate metabolism after insulin in diabetes, [Sydenstricker & others] *2137

deficiency, neurologic aspects, [Arling & others] *2105

factors in, 863-E

graphic description of components, [Arling & others] *2107

prevents maternal-infant anemia, [Gottlieb] 181-ab

research, Mead Johnson Award for, 1423

treatment of presenile psychosis, (Alzheimer's disease) 1132

B₁: See also Acid, nicotinic; Thiamin

B₁ and cardiovascular disorders of pregnancy, [Bickel] 2275-ab

B₁ deficiency and premenstrual tension, 165

B₁ deficiency in chronic alcoholic addicts, [Bickel] 1368-ab

B₁ deficiency in hookworm anemia, [McKenzie] 723-ab

B₁ deficiency relation to diabetic neuritis, priority, [Wohl] 164-C

B₁ determination: enzymic reaction, 504-E

B₁ need for adding to staple American foods, [Covgill] *2146

B₁ required in pregnancy, lactation, in infants, etc., [Arling & others] *2109

B₁ restored to cereal products, including wheat flour, [Covgill] *2150

B₁ (synthetic), prolonged intramuscular injections; untoward effects? 530

B₁ treatment of acute alcoholic delirium [Karnosh] *1325

B₁ treatment of alcoholic polyneuritis, [McGeel] 362-ab

B₁ treatment of alimentary edemas of infants, [Kollmann] 727-ab

B₁ treatment of insomnia, [Karnosh] *1325

B₁ treatment of neuritis, [Arling & others] *2105

B₁ treatment of nonanginous precordial pain, [Mola] 2099-ab

B₁ treatment of postdiphtheric paralysis, [Felge] 1180-ab

B₂: See also Riboflavin

B₂ complex deficiency relation to indole in anemia, [Rhoads] *299

B₂ complex diets (high) in pneumonia and typhoid, [Rhoads] *301

VITAMINS B COMPLEX--Continued

B₂ deficiency, eye symptoms in, [Pock-Steen] 2102-ab

B₂ role in sensitivity to insulin, [Mainzer] 986-ab

B₂ (autidermatitis factor; acrodynia rat factor; filtrate factor) 683-E; 863-E

VITAMINS C: See also Acid, ascorbic

aging eye and, [Bouton] 261-ab

deficiency and intestinal fusospirochetosis, [Woodsey] 2183-ab

deficiency in spinal arthritis, [Baker] 1163

-ab

deficiency, monoethanolamine salt of ascorbic acid for, [Lozner] 718-ab

deficiency (real and so-called), [Kreuzwende] 370-ab

dich von dem Borne] 370-ab

effect on blood coagulation, [Fasoli] 726-ab

effect on blood in fever, [Falke] 1082

loss and consumption in, [Hausberger] 2192-ab

loss in orange juice on standing, 352

supply, intracutaneous test for, [Beck] 2009

-ab

treatment of Addison's disease, [Pojer] 2190

-ab

treatment of burns, [Einhauser] 186-ab

treatment of hemorrhages of gums, 83; [Fasoli] 726-ab

treatment of insomnia, [Karnosh] *1326

treatment of lead poisoning, [Holmes] 1444

-ab

treatment of pulmonary tuberculosis, [Baksh] 1076-ab

VITAMINS D: See also Cod Liver Oil; Halibut Liver Oil; Viosterol

activity, effect of phosphorus on, [O'Brien] 1994-ab

Cooperative Committee recommendations, *592; 598-E

D₂ and D₃ in rickets treatment, [Morris] 2437

-ab

deficiency and dental caries, [Taylor] 542

-ab

effect on urinary calculi, [Plocks] *1468

effect on wound healing, 2254

treatment, massive dose, [van Ormondt] 2001

-ab

treatment of arthritis, serum phosphatase in, [Smith] 1841-ab

treatment of hypoparathyroidism, [Anderson] 1367-ab

treatment of senile osteoporosis, [Rosenfeld] 440-C

treatment of spinal osteomalacia, [Meulengracht] 1923-ab

VITAMINS E, action on wound healing in liver and spleen, [Bartolomucci] 1079-ab

deficiency, creatinuria in, di-alpha-tocopherol for [Verzár] 1448-ab

effect on ovary-thyroid-relationship, [Schnelder] 273-ab

treatment of sterility, 521

VITAMINS F, misuse of term, Cooperative Committee on, *593; 598-E

VITAMINS H in liver extract, [Marshall] 1519

VITAMINS K, (Council report) [Snell & Butt] *2056

absorption from digestive tract, effect of bile, [Butt & others] *385

chemical nature, 417-E; [Snell & Butt] *2057

crystalline form, first isolation, [Dolsy] 389

-ab

deficiency in infants, 1504; [Dam] 1846-ab

deficiency, new test using thromboplastin, [Smith & others] *381; 2173

hemorrhage tendency and, [Olson] 1446-ab; [Dam] 1846-ab

Intramuscular use, [Cheney] 538-ab

intravenous and intramuscular use, [Sueli & Butt] *2057; *2059

methods of giving, clinical studies on, [Tage Hansen] *1875

phthiocol having activity of, [Smith & others] *383; 417-E; [Snell & Butt] *2057; *2059

Prothrombin Deficiency; Determination: See Blood coagulation

structure, [Snell & Butt] *2057

treatment of hemorrhagic disease of newborn, send] 1518-ab

treatment of hemorrhagic disease of newborn, [Nygaard] 2278-ab

treatment of jaundiced patients, [Smith & others] *380; [Butt & others] 1845-ab; [Smith] 1361-ab; [Koller] *2223
